
Block 1: Personality and Personality Development

Unit 1: Definition and Concept of Personality and Personality Development

- **Definition and Concept of Personality**
    - **Layperson's View**: Often understands personality in terms of being **good looking, attractive, or pleasant in interaction**. Psychologists consider this inadequate as it limits important behaviors and implies some people lack personality.
    - **Scientific View (Psychologists)**: Explain personality in terms of **individuality and consistency**.
        - **Individuality**: Each person is unique ("like no other person").
        - **Consistency**: A person behaves somewhat consistently across different situations and over time, leading to the notion of **personality traits**.
        - **Combined Definition**: Personality is the **distinctive and unique ways** in which each individual thinks, feels, and acts, characterizing their response throughout life. It refers to **relatively permanent traits, dispositions, or characteristics within a person** that provide consistency to behavior.
    - **Allport's Definition**: Personality is the **dynamic organisation within the person of psychophysical systems that determine the unique adjustments to one's environment**. He analyzed 50 definitions to arrive at this.
    - **Distinctions**:
        - **Character**: Refers to **value judgments** about a person's moral values or ethical behavior.
        - **Temperament**: Refers to **inborn enduring characteristics** like adaptability or irritability.
        - **Both character and temperament are vital parts of personality**.
- **Personality Development - Factors**
    - Psychologists broadly group factors influencing personality development into three categories, also called **determinants of personality**:
        - **Biological Factors**
        - **Psychological Factors**
        - **Environmental Factors**
    - **Personality Development Equation**: Personality Development = **Physical determinants × Psychological determinants × Environmental determinants**. This suggests an unanimity among psychologists that biological factors provide a boundary, within which psychological and environmental factors shape personality.
- **1.3.1 Biological Factors (Physical Determinants)**

- Emphasize that **physique and body functioning** directly influence personality.
- **Body Build**: Influences what an individual can or cannot do and their reactions to others' body builds.
  - **Ectomorphs**: Tall and thin; generally superior in speed and endurance to endomorphs.
  - **Endomorphs**: Round and soft body builds.
  - **Mesomorphs**: Strong and muscular; superior to both ectomorphs and endomorphs in speed, endurance, and agility.
  - Body build affects **self-concept** (favorable or unfavorable).
- **Physical Attractiveness**: Attractive persons are more appealing and people tend to be more tolerant in their attitudes and judgments toward them. For example, an attractive worker is more likely to get promoted sooner than an unattractive one, even if less conscientious.
- **Homeostasis**: Refers to the **maintenance of a stable internal environment** (e.g., normal temperature, blood sugar, blood pressure).
  - **Direct Impact**: When stable, leads to relaxed, controlled, socially acceptable behavior. Disturbances lead to irritability, indigestion, insomnia.
  - **Indirect Impact**: Affects personality through a person's reaction to others' attitudes about their physical state. E.g., if superior size is viewed favorably, it's positive; if ridiculed, it's unfavorable.
  - **Examples**: High blood sugar can lead to depressive states; Vitamin B complex deficiency to increased emotionality and depression; High blood pressure to neuroticism; Anoxia to emotional outbursts, mental confusion, self-criticism.
- **Physical Defects**: Can have direct and indirect impacts.
  - **Alfred Adler's theory of organ inferiority** was the first scientific study on this.
  - **Obesity**: A handicap in social relationships, leading to feelings of inferiority and being socially scorned. Massively obese individuals may become more disturbed due to less self-satisfaction and adverse comments from others.
- **Health Conditions**: Good health is a personality asset, poor health a liability. Personality changes due to poor health can persist even after recovery, especially during childhood's formative stages. Illnesses in early childhood can root personality changes and disturbances in adolescence and adulthood.
  - **Examples**: Diabetes can cause tension and anxiety, leading to aggression. Irregular menstrual cycles can lead to emotional instability, irritability, and depression, affecting social adjustment and self-concept.

- **1.3.2 Psychological Factors**

  - Influence personality through various life adjustments and others' judgments based on intellectual achievements.
  - **Intellectual Determinants**:

        - **Bright individuals** (men and women) generally make **better personal and social adjustments**. They are introspective, thoughtful, creative, adventuresome, concerned with problems/meanings/values, show wider interests, and have better self-control.
        - **Very superior intelligence** can **unfavorably affect personality** by creating special problems, leading to traits like negativism, intolerance, chicanery habits, emotional conflicts, solitary pursuit, self-sufficiency, and dominance. Influences development of values, morality, and humanity.
    - **Emotional Determinants**: Affect personal and social adjustment.
        - **Dominant Emotions**: Predominance of pleasant emotions (cheerfulness) or unpleasant (apprehension) affects personality.
        - **Emotional Balance**: Pleasant emotions outweighing unpleasant ones is essential for good social and personal adjustment.
        - **Emotional Deprivation**: Lack of pleasant emotions (love, happiness, curiosity) leads to poor personal and social adjustment. Its impact depends on extent, duration, and age of occurrence. A common effect is **emotional insecurity**, leading to adolescent/adult rebellion against authority.
        - **Excessive Love and Affection**: Can have negative psychological effects, leading to neurotic disorders, spoiling the child, and making individuals problematic adolescents. Overprotective mothers can turn children into immature and dependent adults.
        - **Emotional Expression**: Expressing emotions in socially approved ways leads to favorable judgment and a good mirror image of the self, restoring homeostasis.
        - **Repression**: Repressing emotions (anger, fear, jealousy, envy) can make individuals gloomy and morbid, leading to extreme laziness, lack of interest in people, and mood vacillation.
        - **Emotional Catharsis**: Release of unexpressed emotions helps restore physical and mental homeostasis, allowing for realistic self-judgment.
    - **Self-disclosure**: Basic to mental health, leading to a healthy personality and socially desirable reactions from others.
    - **Emotional Stress**: Anxiety, frustration, jealousy, envy affect personality. Intense stress can lead to excesses like overeating or drug use to dull insecurity. Low self-esteem individuals are more adversely affected by emotional stress than those with high self-esteem.
    - **Aspiration and Achievements**:
        - **Aspiration**: Longing for and striving for something higher than one's current status; ego-involved goals. The more ego-involved, the greater the impact on behavior and personality.
        - **Forms of Aspiration**: Positive (success), negative (avoid failure), realistic, unrealistic, remote, immediate. Remote and realistic aspirations provide stronger motivation than immediate and unrealistic ones.

        - **Level of Aspiration**: Discrepancy between achieved and hoped-for goals. Large discrepancies, especially with failure, severely damage self-concept and lead to self/social judgment of failure. High aspirations are not necessarily damaging; can be motivating or a form of wishful thinking if kept in fun.
        - **Achievements**: Evaluated objectively (vs. peers) or subjectively (vs. aspiration).
            - **Success**: Positive attitude towards achievement, favorable self-concept, raises self-esteem, increases self-confidence, leads to more realistic goal setting. However, too much early success can weaken motivation and cause jealousy/resentment in others.
            - **Failure**: Ego-deflating, undermines self-confidence and self-esteem, destroys belief in ability to achieve. Severe/repeated failure causes stress, anxiety, tension, psychosomatic illness, or defeatist attitude. Not achieving desired goals/social recognition when hoped for is most damaging, especially if competitors succeed.
            - **Early Success/Recognition**: Can have a favorable impact on self-concept, but extreme favorability might lead to delusions of grandeur or superiority complex, damaging social judgment.
- **1.3.3 Environmental Factors**

    - **Social Acceptance**: Major determinant. Social group's judgment based on conformity influences self-evaluation and self-concept.
        - Influence depends on how well accepted one is and the importance attached to social acceptance.
        - High social acceptance leads to congenial, friendly spirit. Highly accepted individuals are more outgoing, flexible, active, daring, but may fail to establish close relationships or show emotional warmth due to a feeling of superiority.
        - Social rejection leads to resentment, depression, unhappiness, and possibly antisocial behavior (juvenile delinquency/criminality). Favorable early social experiences lead to social personality, unfavorable to unsocial/antisocial.
    - **Social Deprivation**: Being deprived of social contacts, love, and affection. Causes social isolation and adverse effects on personality. Most damaging for the very young (failure to develop healthy personality) and the elderly (self-bound, selfish). More damaging for those who need social contact for happiness than self-sufficient individuals. Prolonged deprivation leads to unhealthy social attitudes and mental illness.
    - **Educational Factors**: Schools, colleges, and teachers significantly impact personality.
        - Impact determined by students' attitudes towards school, peers, teachers, and value of education. Favorable attitudes lead to enjoyment, warm

relationships, stronger self-confidence, and self-esteem. Unfavorable attitudes have reverse effects.
        - Emotional climate of institution affects motivation, classroom behavior, emotional reactions, and student-teacher relationships. Teacher-student relationship, based on teacher's treatment and disciplinary techniques, affects academic work and self/social evaluation, boosting self-concept.
    - **Family Determinants**: Maximal influence at all ages.
        - **Direct Influence**: Child-training methods (e.g., strict parents lead to dependence on external controls, impulsiveness outside direct control) and communication of interests, attitudes, values.
        - **Indirect Influence**: Identification with parents (similar personality patterns) and imitation (e.g., living with anxious parents leads to nervousness and temper outbursts; warm parents lead to social, gregarious, welfare-oriented individuals).
    - **Emotional Climate of Home and Ordinal Position**:
        - **Emotional Climate**: Favorable home climate leads to calm reactions to problems and tolerant, cooperative interactions with people. Friction/conflict leads to hostility and aggressive reactions.
        - **Ordinal Position**:
            - **Firstborns**: More conforming, dependent, affiliative, susceptible to group pressures, introverted. Successful firstborns may be selfish, self-centered, critical of others, stemming from insecurity caused by parental attention shifting to later-borns.
            - **Lastborns**: Dependency, affiliative need, lack of self-confidence, low frustration tolerance, defiance of authority, weaker achievement motivation. Less family-oriented, more peer-oriented, better social adjustment, more popular among peers.
            - **Middle/Second Borns**: Generally less family oriented and more peer oriented. Develop traits from peer relationships that lead to better personal and social adjustment, making them more popular than first or lastborns.
    - **Size of the Family**:
        - **Larger Families**: Parents have less time for each child, leading children to be more independent and mature earlier. However, often adopt authoritarian control methods, producing resentment and rebellion.
        - **Small Families**: Parents devote more time, providing guidance, fostering self-confidence, self-assurance, and eliminating feelings of inadequacy. However, strict competition for parental attention can cause jealousy and envy, especially against firstborns, damaging self-concept.

Unit 2: State/Trait Approaches to Personality

- **2.2 Type Approaches to Personality**

    - Classify behavior into **discrete, all-or-nothing categories**.

- **Hippocrates/Galen (Four-Humor Theory)**: Classified individuals into four types based on dominance of bodily fluids (blood, phlegm, black bile, yellow bile), each linked to a temperament (Sanguine, Phlegmatic, Melancholic, Choleric). **Considered baseless today** as personality is not driven by bodily fluids.
- **William Sheldon (Somatotype)**: Related physique to temperament.
  - **Ectomorphic** (thin, long, fragile): Artistic, brainy, introverted.
  - **Endomorphic** (fat, soft, round): Relaxed, fond of eating/sleeping, sociable.
  - **Mesomorphic** (muscular, strong, rectangular): Affective, dominant, energetic, courageous.
  - **Limitations**: Failed in predicting individual behavior; people don't fit neatly into three types.
- **MBTI (Myers-Briggs Type Indicator)**: Modern typology based on Carl Jung's theory. Assesses four dimensions:
  - **E or I** (Extraversion-Introversion).
  - **S or N** (Sensing or Intuition).
  - **T or F** (Thinking-Feeling).
  - **J or P** (Judgment-Perception) - Myer's distinction on external world orientation.
  - Identifies 16 personality types. Example: ESFP (outgoing, easygoing, accepting, friendly, good common sense).
  - **Critics**: Categories are distinct, but people should be described by actual scores on dimensions, not forced into types.
- **Overall Limitations of Type Approach**: Fails to provide satisfactory classification; robs uniqueness of persons. Psychologists prefer traits over types.

- **2.3 Trait Approaches/Theories**
  - Explain personality in terms of **traits, defined as relatively stable and consistent personal characteristics**.
  - **Assumptions**: Continuous dimensions (e.g., warmth, extraversion) that vary in quality and degree. Aims to explain personality differences, measure traits, and predict behavior.
- **2.3.1 Allport's Trait Approach**
  - **Key Figure**: Considered one of the most important and influential personality theorists.
  - **Lexical Approach**: Recorded 17,953 words describing personal traits from the English Dictionary (Allport & Odbert, 1936).
  - **Core Belief**: Traits are the **building blocks of personality and source of individuality**. He was an **idiographic trait theorist**, believing each person has unique and common traits forming a unique combination.
  - **Nature of Traits**: Exist but are invisible, located in the nervous system (Ryckman, 1993). Inferred by observing consistency in behavior. Dissimilar stimuli can arouse a trait, which manifests through various responses.

        - **Example**: Shyness inferred from inability to form friendships, avoidance of social gatherings, enjoyment of solitary activities, unwillingness to participate in discussions.
    - **Categories of Traits**:
        - **Common Traits**: Shared with many others in a culture (e.g., being quiet, respecting seniors, polite behavior in Indian culture).
        - **Individual Traits (Personal Dispositions)**: **Unique to the person**, more important than common traits.
            - **Cardinal Traits**: So **pervasive, dominant, and outstanding** that every behavior seems traceable to its influence. Few people have them, but those who do are known by them (e.g., Mahatma Gandhi's peace-loving and non-violence).
            - **Central Traits**: Generally listed in a recommendation letter; **5 to 10 most outstanding traits** around which a person's life focuses (e.g., friendliness, dominance, self-centeredness).
            - **Secondary Traits**: Less conspicuous, less consistent, less generalized, less relevant to personality definition (e.g., food habits, hair style, specific attitudes).
    - **Dynamic Nature**: All traits possess **motivational power**. Intensively experienced individual traits are more motivational; less intensively experienced ones are more stylistic.
    - **Proprium (Self)**: Integrates the traits, giving personality unity and consistency. Develops continuously from infancy to death.
- **2.3.2 Cattell's Trait Approach**

    - **Definition**: Personality is a **pattern of traits** for understanding and predicting behavior. Traits are **relatively permanent and broad reaction tendencies**.
    - **Distinctions of Traits**:
        - **Surface Traits vs. Source Traits**:
            - **Surface Traits**: Observable qualities of personality (e.g., kindness, honesty, helpfulness). Allport called these central traits.
            - **Source Traits**: **Deeper, more general underlying personality factors** responsible for inter-correlation among surface traits. Make up the basic structure of personality and are better predictors of behavior. Everyone possesses them, but in different amounts (e.g., intelligence).
            - Cattell found 23 source traits in normal persons, studied 16 in detail for his **Sixteen Personality Factor (16PF) Questionnaire**. Later proposed 7 new factors. Derived 12 psychopathological traits for **Clinical Analysis Questionnaire (CAQ)**.
        - **Constitutional Traits vs. Environmental-Mold Traits**:
            - **Constitutional Traits**: Determined by **nature or biology**.
            - **Environmental-Mold Traits**: Determined by **nurture or experience**.

            - Most surface traits are a mixture of both. Used **MAVA (Multiple Abstract Variance Analysis)** to assess genetic vs. environmental determination.
        - **Ability, Temperament, and Dynamic Traits**:
            - **Ability Traits**: Person's **skill in dealing with the environment and goals** (e.g., intelligence).
            - **Temperament Traits**: **Stylistic tendencies** showing how a person moves towards a goal (e.g., moody, irritable, easygoing).
            - **Dynamic Traits**: Person's **motivation and interest** that set them in action toward a goal (e.g., power-seeking, ambitious). Important types:
                - **Attitudes**: Dynamic surface traits displaying specific manifestations of underlying motives.
                - **Ergs**: **Constitutional dynamic source traits**, innately determined but modifiable impellents of behavior (e.g., hunger, sex, gregariousness, parental protection).
                - **Sentiments**: Environmental-mold dynamic source traits, learned attitudes towards objects.
- **2.3.3 Eysenck's Type/Trait Hierarchy**
    - **Core Belief**: Personality is largely determined by **genes**, with minimal environmental role. Personality is a **stable and enduring organization of character, temperament, intellect, and physique**.
    - **Hierarchical Organization**:
        - **Lowest Level**: Single responses (actions, thoughts).
        - **Habits**: Regularly occurring responses form habits.
        - **Traits**: Related habits form traits.
        - **Types (Superfactors)**: Several traits clustered together constitute a type. Types are most abstract, based on intercorrelations among traits.
        - **Example**: "Extraversion" type based on traits like liveliness, sociability, activity, excitability, which are inferred from habitual responses (going to club, talking to people), based on specific observable responses (actual club attendance).
    - **Three Major Factors/Dimensions**: Derived from factor analyses.
        - **Extraversion/Introversion**:
            - **Extraverts**: Sociable, impulsive, like excitement, oriented toward external reality.
            - **Introverts**: Introspective, oriented toward inner reality, prefer well-ordered life.
        - **Neuroticism/Stability**:
            - **Neurotics**: Emotionally unstable, exhibit anxiety disproportionate to reality. May show obsessional/impulsive symptoms, unreasonable fears. Psychopaths also in this group (fail to assess consequences, antisocial).

        - **Stable**: Emotionally balanced.
    - **Psychoticism/Impulse Control**:
        - **Psychotics**: Insensitive to others, hostile, cruel, inhuman. Eysenck believed them to be **creative**.
- **Assessment**: **Eysenck Personality Questionnaire (EPQ)** measures these three dimensions.
- **Physiological Basis of Traits**:
    - **Inhibition Theory (Earlier)**: Explained differences in extraversion/introversion.
        - **Extraverts**: Stronger inhibitory processes, weak excitatory processes; strong nervous system, high tolerance for stimulation. Seek excitement.
        - **Introverts**: Strong excitatory processes, weak inhibitory processes; weak nervous system, low tolerance for stimulation. Avoid strong stimulation, prefer aloof activities.
    - **Arousal Theory (Later)**: Replaced inhibition theory, identifying physiological systems.
        - Differences due to **Ascending Reticular Activating System (ARAS)** activity.
        - **Introverts**: Innately higher levels of ARAS arousal, more sensitive to stimulation.
        - **Neuroticism**: Seat of neuroticism in **visceral brain (limbic system)** structures (hippocampus, amygdala, etc.) involved in generating emotionality. Neurotics have lower thresholds for visceral brain activity and greater sympathetic nervous system responsivity, leading to overreacting to mild stimulation.

- **2.3.4 Guilford's Trait Theory**

    - **Definition**: An individual's personality is nothing but the individual's **unique pattern of traits**. Trait is any **distinguishable, relatively enduring way one person differs from another**.
    - **Seven Modalities of Traits**: Identified using factor analysis.
        - **Morphological Traits**: Physical attributes (physique, head size, limb length).
        - **Physiological Traits**: Physical functions (heart rate, breathing rate, hormone level, blood sugar).
            - Together, morphological and physiological traits are called **somatic traits**. Little substantial relationship between them, though Sheldon reported high correlation.
        - **Needs**: Relatively permanent dispositions motivating toward certain conditions (e.g., prestige, food).
        - **Interests**: Person's generalized behavior tendency to be attracted by certain stimuli or to perform activities.

        - **Attitudes**: Disposition to favor or not favor a social object or action; involve belief, feelings, action (cognitive, affective, conative).
            - Needs, Interests, and Attitudes are **hormetic (adaptive responses) dimensions**, instigating action because they are related to motivation.
        - **Aptitudes**: How well an individual can perform an activity; more specific than abilities (all aptitudes are abilities, but not vice-versa).
            - Three primary aptitudes: **Perceptual aptitudes** (sense modalities), **Psychomotor aptitudes** (physical educators, dance instructors), and **Intelligence** (general aptitude).
            - **Structure-of-intellect model for intelligence**: Originally 120 factors, expanded to 180 factors (6 operations × 6 products × 5 contents).
        - **Temperament**: Manner in which an individual performs a behavior (impulsive, tolerant, deliberate, critical). Assessed by inventories like **Guilford-Zimmerman Temperament Survey (GZTS)**, which assesses 10 bipolar traits.
    - **Three Levels of Trait Generality**:
        - **Hexic Level**: Trait displayed **only in specific situations** (e.g., a generally shy person showing dominance in a competition). Determines specific actions.
        - **Primary Trait Level**: Manifested in a **broader range of behavior** (e.g., Shyam shows dominance and aggression most of the time).
        - **Type Level**: When a person's behaviors generally revolve around any single disposition. Types are composed of primary traits with positive intercorrelations (e.g., extravert type recognized by sociability, impulsiveness).
- **2.3.5 Five Factor Model (Big Five / FFM / OCEAN)**
    - **Most talked about trait approach today**. Proposes five broad personality factors, each composed of a constellation of traits.
    - **Goldberg (1981)**: Possible to structure individual differences among personality traits. Big Five subsumes a large number of specific traits and are as broad/abstract as Eysenck's superfactors.
    - **The Five Dimensions (McCrae and Costa, 1987)**: Acronym **OCEAN** for easy memory.
        - **O - Openness (to Experience)**: Assesses proactive seeking and appreciation of experience for its own sake, tolerance for new/unfamiliar. High scorers: good-natured, warm, sympathetic, cooperative. Low scorers: unfriendly, aggressive, unpleasant, argumentative, cold, hostile.
        - **C - Conscientiousness**: Assesses person's degree of **organization, persistence, and motivation in goal-directed behavior**. Describes task and goal-directed behaviors and impulse control. High scorers: dependable, organized, hardworking, responsible, reliable, thorough. Low

scorers: undependable, disorganized, unreliable, impulsive, irresponsible, lazy.
        - **E - Extraversion**: Assesses **quality and intensity of interpersonal interaction**. High scorers: sociable, active, talkative, person-oriented, optimistic, fun-loving, affectionate. Low scorers: reserved, sober, aloof, task-oriented, retiring, quiet.
        - **A - Agreeableness**: Assesses person's **quality of interpersonal orientation**, ranging from compassion to antagonism in thinking, feeling, and action. High scorers: soft-hearted, good-natured, trusting, helpful, straightforward, forgiving. Low scorers: cynical, suspicious, uncooperative, vengeful, irritable, manipulative.
        - **N - Neuroticism**: Assesses **adjustment vs. emotional instability**. High scorers: prone to emotional instability, experience negative emotion, moody, irritable, nervous, insecure, hypochondriacal. Low scorers: calm, relaxed, unemotional, hardy, self-satisfied.
    - **Assessment**:
        - **Transparent Bipolar Inventory** (Goldberg, 1992).
        - **NEO-Personality Inventory (NEO-PI-R)** (Costa and McCrae, 1992): Originally N, E, O, later added A, C. Consists of 240 items (5 factors × 6 facets × 8 items). McCrae and Costa (1990) believe these five factors are sufficient and parsimonious for describing personality.
    - **Evaluation and Criticisms**:
        - **Support**: Longitudinal studies show traits are **stable for 3 to 30 years**, universal features of adult personality.
        - **Criticism**: Does not explain **causes or development of personality**; simply identifies and describes characteristics correlated with behavior. Consistency of behavior across situations is low and not predictable solely from traits.
        - **Person-Situation Debate**: Walter Mischel (1968) initially claimed **situation, not traits, determines behavior**. Later modified his position, proclaiming behavior is shaped by **both the person (traits) and the situation**. Other psychologists support internal traits influencing behavior across situations.

Unit 3: Assessment of Personality

- **3.2 Needs and Aims of Assessment**

    - **Definition**: Personality assessment refers to the **estimation of one's personality makeup**, including characteristic behavior patterns and salient/stable characteristics.
    - **Purpose**: Varies by purpose (self-understanding, classification of traits, diagnosis of disorders).

- **Methods**: Broadly categorized as **subjective, objective, and projective**. Objective tools are important for unbiased assessment, revealing surface and underlying aspects.

- **3.3 Methods of Personality Assessment**

  - **3.3.1 Interviews**: Interviewee answers questions from a professional, structured or unstructured.

    - **Limitations**: Interviewees can misinform, lie, distort, or hide information for social desirability. Interviewer biases (personal beliefs, prejudices) can impede interpretation. **Halo effect** (first impression influences all subsequent interpretations) is another problem.

  - **3.3.2 Projective Techniques**:

    - **Core Idea**: Assumed to reveal **central aspects of personality that lie in the unconscious mind** (motivations, desires, fears, complexes).

    - **Distinguishing Feature**: **Unstructured tasks** permitting an endless range of responses.

    - **Underlying Hypothesis**: How individuals perceive and interpret test material reflects fundamental psychological functioning; test material is a "screen" for projecting thoughts, anxieties, conflicts, needs.

    - **Process**: Client tells what they see in ambiguous stimuli, projecting unconscious concerns. Serve as diagnostic tools for hidden issues.

    - **History**: Began with Leonardo da Vinci (15th century); Word association test by Gallon (1879), used by Carl Jung. Frank (1939, 1948) introduced the term "projective method".

    - **Advantages**: Opportunity to project attributes not revealed in normal conversation. Disguised testing procedures (test takers unaware of psychological interpretation). Focus on composite picture rather than separate traits. Effective for revealing latent/hidden aspects of personality.

    - **3.3.3 Classification of Projective Techniques (Frank's - with limitations)**:

      - **Constructive**: Examinee constructs a specific task (e.g., drawing a human figure).
      - **Constitutive**: Examinee imposes structure on unstructured materials (e.g., Rorschach Ink Blot).

        - **Cathartic**: Examinee releases wishes/conflicts through manipulative tasks.
        - **Interpretative**: Examinee adds detailed meaning to a situation (e.g., TAT, Word Association Test).
        - **Refractive**: Examinee depicts personality through drawing, painting (e.g., graphology).
        - **Limitation of Frank's Classification**: Significant overlap, same test in multiple categories.
- **3.3.4 Association Technique**: Examinee gives responses in the form of associations to stimulus material (e.g., **Word-Association Test**: first word that comes to mind after hearing stimulus word).

- **3.4 Ink Blot Techniques**:

    - **Rorschach Inkblot Test (Hermann Rorschach, 1921)**: 10 inkblots (5 black, 5 colored). Subject states what each inkblot looks like. Responses scored on factors like color, shape, movement, whole/part blot, and content. Used for personality description, mental disorder diagnosis, behavior prediction.
        - **Procedure**: Performance proper (reaction time, card position, verbatim response recording, total time for card, response productivity ratio), Inquiry (collect info for scoring), Scoring (location, determinants like form/color/shading/movement, form quality, content categories like human/animal figures, popularity score). Qualitative interpretation of scores (whole responses with conceptual thinking, color responses with emotionality/fantasy).
        - **Limitations**: Variability in responses, examiner effects, interdependence of scores. Reliability and validity questions. Not originally developed as psychometric tool.
    - **Holtzman Inkblot Test (HIT) (Holtzman et al., 1961)**: Developed to address Rorschach's difficulties (unlimited responses, poor scorer reliability). Two parallel forms (A, B) with 45 cards each. One response per card. Better standardized, highly satisfactory scorer reliability and validity. HIT 25 variant successful in diagnosing schizophrenia.
- **3.4.1 Construction Techniques**: Examinee constructs a story from stimulus material within a time limit (themes and mode of responding are relevant).

    - **Thematic Apperception Test (TAT) (Henry Murray, Morgan & Murray, 1935)**: 20 black and white ambiguous pictures. Client tells a story (what's happening, what led to it, future). Psychologist

interprets, looking for revealing statements and projections of hidden emotions onto characters. Analyzed in reference to Murray's "needs" (achievement, affiliation, aggression) and "press" (environmental forces).
        - **Draw-A-Person and House-Tree-Person tests** also included.
        - **Limitations of TAT**: High variations in administration and scoring make psychometric investigation difficult.
    - **3.4.2 Completion Techniques**: Incomplete sentences presented for examinee to complete as desired.

        - **Example**: "I want _____", "I feel excited about _____".
        - **Rotter's Incomplete Sentences Blank** is an example. Considered semi-projective.
    - **3.4.3 Expressive Techniques**: Manipulative tasks used to depict personality; examiner pays attention to how materials are manipulated.

        - **Examples**: Role playing, finger painting, play, drawing.
    - **3.4.8 Limitations of Projective Tests (General)**:

        - **Subjective nature**: Interpretation requires deep analytic and artistic traits.
        - **Reliability and validity problems**.
        - **No standard grading scales**.
        - **Varying moods** can influence answers.
        - **Situational variables** (e.g., examiner's physical characteristics, changed instructions) can influence responses.
        - **Eysenck (1959)**: Relationship between projective indicators and personality traits not empirically demonstrated. Many studies have methodological flaws. Not guided by consistent, meaningful, testable theories. Poor predictive ability for life success/failure. No evidence of relationship between global interpretation by experts and psychiatrists.
- **3.5 Behavioural Assessment**:

    - **Behaviorist Assumption**: Personality is a composite set of learned responses to environmental stimuli.
    - **Methods**:
        - **Direct observation**: Psychologist observes client in daily routines at home, school, work.
        - **Rating scales**: Psychologist or client assigns numeric rating to specific behaviors.
        - **Frequency counts**: Counts frequency of certain behaviors in a specified time.

        - **Limitations**: **Observer bias** is major. Lack of control over external environment.
    - **3.6 Personality Inventories**:
        - **Definition**: Printed form with statements/questions about human behavior, requiring **specific, standardized, close-ended answers** (e.g., "yes," "no," "cannot decide").
        - **Nature**: **Objective** in nature, reducing observer and interpretation bias.
        - **Examples**:
            - **Cattell's 16PF**.
            - **NEO-PI (Costa and McCrae, 2000)** - based on Five Factor Model.
            - **Myers-Briggs Type Indicator (MBTI)** - popular, based on Jung's dimensions (I/E, S/I, T/F, P/J).
            - **Eysenck Personality Questionnaire (EPQ) (Eysenck & Eysenck, 1993)**.
            - **California Psychological Inventory (Gough, 1995)**.
            - **Sixteen Personality Factor Questionnaire (Cattell, 1994)**.
        - **3.6.1 The MMPI-2 (Minnesota Multiphasic Personality Inventory, Version-II)**:
            - **Most common personality inventory**, specifically tests **abnormal behavior patterns**.
            - **Contents**: 567 statements (e.g., "I believe I am being plotted against"). Answers: "true," "false," or "cannot say".
            - **Scales**: 10 clinical scales (assess disorders like schizophrenia, depression) and 8 validity scales (ascertain honesty of response).
        - **3.6.2 Limitations of Personality Inventories**:
            - **Faking**: People may fake answers or respond in socially acceptable ways.
            - **Response sets**: Some people follow a regular course of answering without actual consideration.

Unit 4: Key Issues in Personality

- **4.2 Genes and Personality**
    - **Nature vs. Nurture Debate**: Oldest dispute in psychology, regarding the **relative importance of inherent traits (nature) versus personal experiences (nurture)** on personality development.
    - **Nature Theory (Heredity)**: Genetic predispositions and instincts drive behavior. Abstract traits (intelligence, personality, aggression, sexual orientation) are encoded in DNA (behavioral genes, "gay gene").
    - **Nurture Theory (Environment)**: Behavioral aspects originate from environmental forces and upbringing. John Watson (phobias via classical conditioning) and B.F. Skinner (human behavior conditioning) were strong proponents. Child is a "blank slate" (tabula rasa).

- **Interactionism**: Both nature and nurture are right; nature provides inherent abilities, nurture reshapes them.
- **Twin Studies**: Important tool for resolving debate.
    1. **Identical (Monozygotic) Twins**: Exact duplicates of genotypes; best for indicating biological disposition effects.
    2. **Fraternal (Dizygotic) Twins**: Share half genes; good basis for comparison.
    3. **Findings**: Partial correlation between attitudes and genetic factors. Non-shared environmental experiences are the strongest cause of attitude variances, overshadowing genetic predispositions and shared environment. Genotype-environment interaction: how people with same genotypes respond to similar environments (Type I: environment more significant with low genotype scores for a trait; Type II: opposite).
- **Adoption Studies**:
    1. **Infant Shyness**: Biological mothers' shyness correlated with adopted babies' shyness, indicating genetic link.
    2. **Anti-social Personality Disorder**: More prevalent in adopted children with biological risk factors. High incidence of criminal tendencies if both biological and adoptive parents have criminal backgrounds.
    3. **Interpretation Difficulty**: Genetic factors can be "simulated" if adoptive environment resembles biological environment.
- **Family Studies**: Less valid than twin/adoption studies, but used to determine **risk of inheritance of mental disorders** through molecular genetic studies.

- **4.3 The Person-Situation Controversy**

    - **Sparked by Mischel (1968)**: Argued that **personality traits do not predict actual behavior** well, and cross-situational consistency of behavior is low (.20-.30). Concluded situations are better predictors.
    - **Epstein (1983)**: Traits predict **aggregates of behaviors** (multiple observations), not single behaviors.
    - **Trait Psychologists' Response**: Low correlations don't mean situational variables are more valuable. Actual personality-behavior correlation found higher than .40. Personality is a stronger predictor across all situations, but not for an individual's behavior at a specific time/situation. Traits are useful psychological tools for prediction.
    - **Behavioral Consistency Controversy**: Another view that traits vary by situation; no consistent traits reflected by individual's responses.
        1. **Hartshorne and May (1928) on honesty in children**: Children behaved specifically to the situation, not consistently honest or dishonest.
        2. **Walter Mischel (1968, 1978)**: People learn to make different responses to similar stimuli based on past reinforcements. Significance of situational vs. personality variables determined by **strength/weakness of situation**. Strong situations (uniform interpretation) favor situational variables; ambiguous situations favor personality variables. Later, Mischel (1985)

proposed consistent modes of responding, implying consistency where people behave inadequately.
    - **Resolution**: Behavior shaped by **both the person (traits) and the situation (Interactionist Approach)**. The debate forced a deeper appreciation of personality and a more sophisticated understanding of behavior.
- **4.4 Interactionist Approach to Situation vs. Person Debate**
    - **Formula**: **Behavior = personality × appraisal of the situation**.
    - **Individual Differences**: High self-monitors adapt more to situations, showing less consistency across situations.
    - **Traits and Behavior**: Personality traits exist and are predictive of behavior. Correlations between situations and behavioral outcomes range from 0.36 to 0.42.
    - **Milgram Experiment Example**: Demonstrated strong situational influence where individuals obeyed authority to cause harm, even against their values. All 40 subjects obeyed up to 300 volts, 25 of 40 to 375 volts. 65% never stopped giving shocks, even when the "learner" claimed heart trouble. This suggests an innate tendency to obey authority.
    - **Conclusion of Debate**: Traits don't have cross-cultural consistency for individual behaviors over short periods, but create consistency for wide behavior distributions over time. Situations are not the only thing that matters. New definition: personality is **one's pattern of behavioural stability and change due to the unique combination of having certain traits and being in certain situations**.
- **4.5 Nomothetic Approach Versus Idiographic Approach to Personality**
    - **4.5.1 Nomothetic Approach**:
        1. **Focus**: Personality as **constant, hereditary, and resistant to change**, with minimal environmental influence.
        2. **Goal**: To **calculate and anticipate (foresee) how a person will act** under certain circumstances. Discover **universal behaviors** and general laws that apply to people in general.
        3. **Research Methods**: Relies on **quantitative research** methods (self-report, questionnaires, experiments, correlation, psychometric testing).
        4. **Allport (early view)**: Supported nomothetic approach for scientific progress in trait psychology. Used nomothetically derived traits to describe people.
    - **4.5.2 Idiographic Approach**:
        1. **Focus**: Each individual is a **combined system that can be independently analyzed scientifically**. No general laws are considered important beyond the individual being studied.
        2. **Allport (later view)**: Promoted this approach. Believed a person's traits can be compartmentalized by pervasiveness.

        - **Cardinal Dispositions**: Most pervasive traits, dominating individual behavior (e.g., aggressiveness, calmness).
        - **Central Dispositions**: Pervasive for a given individual (e.g., traits in a recommendation letter).
        - **Secondary Dispositions**: More situation-specific traits.
    3. **Core Idea**: Each person has a **unique pattern of cardinal, central, and secondary traits**, requiring unique examination for understanding.
    4. **Research Methods**: Includes **qualitative methods** (case studies, informal interviews, unstructured observation).
- **4.6 Cross Cultural Issue**
    - **Interwoven Relationship**: Personality and culture are interwoven, but culture is not the sole determiner of personality.
    - **Individualism vs. Collectivism**: Framework to observe differences in national cultures, predisposing traits like personal achievement (individualism) or familial connections (collectivism).
    - **Limitations**: Applying this framework can lead to **stereotyping and misinterpreting** individual personality. Better for describing cultural tendencies as a whole rather than individual traits.
    - **Complexity**: Interplay between personality and culture is complex. Personality can be affected by cultural expectations even in adulthood. Individualism-collectivism is not the only determining factor.
- **4.7 Personality Traits and Five Factor Model**
    - **Definition of Personality Traits (McCrae & Costa, 1990)**: "Dimensions of individual differences in tendencies to show consistent patterns of thoughts, feelings and actions".
    - **Five Factor Model (FFM)**: A parsimonious structure for personality research, developed by McCrae & John (1992).
        1. **Factors**: Neuroticism (N), Extraversion (E), Openness to Experience (O), Agreeableness (A), Conscientiousness (C).
    - **4.7.1 The Five Factor Model Across Cultures**:
        1. Examined with lexical studies in different languages.
        2. **Mixed Results**: E, A, and C factors almost always appear, but N and O sometimes disappear. Unclear if these factors are absent or just expressed differently.
        3. A single set of questionnaire items does not suffice in every culture.
- **4.8 Issues Relating to Theoretical Models**
    - **Problem**: Various theoretical models explain personality from their own perspectives (e.g., Psychoanalytic vs. Behaviorist vs. Humanistic), leading to redundancy, irrelevance, or invalidity of features when considering other models.
    - **Solution**: Need for an **eclectic model** that incorporates multiple viewpoints.
    - **Inherent Controversies (requiring resolution)**:

1. **Free will vs. determinism**: Is behavior driven by freedom or determined forces?.
2. **Uniqueness vs. Universality**: Is each person unique or driven by universal patterns?.
3. **Physiological vs. purposive motivation**: Are we pushed by basic physiological needs or pulled by purpose/goals?.
4. **Conscious vs. Unconscious motivation**: Is behavior determined by conscious or unconscious forces?.
5. **Stage vs. Non-stage theories of development**: Do we pass through predetermined stages (genetics-controlled) or not?.
6. **Cultural determinism vs. Cultural transcendence**: To what extent is personality molded by culture?.
7. **Early vs. Late Personality Formation**: Are personality characteristics established in early childhood or flexible in adulthood?.
8. **Optimism vs. Pessimism**: Are humans basically good or bad?.

Block 2: Theories of Personality

Unit 1: Psychodynamic Theory (Including Horney and Sullivan)

- **1.0 Introduction**
    - **Psychodynamic Perspective**: Theories where human functioning is based on the **interaction of drives and forces within the person**, particularly **unconscious factors** and interaction among personality structures.
    - **Freud's Psychoanalysis**: Original psychodynamic theory.
    - **Psychodynamic Approach (broader)**: Includes Freud's theory and modifications by followers like Jung, Adler, Erikson, Horney, Fromm, Sullivan.
- **1.2 Sigmund Freud’s Psychoanalytic Theory**
    - **Assumptions**:
        1. Behavior and feelings powerfully affected by **unconscious motives**.
        2. Adult behavior/problems rooted in **childhood experiences**.
        3. All behavior has a cause (usually unconscious); thus, **all behavior is determined**.
        4. Personality is **tripartite**: Id, Ego, Superego.
        5. Behavior motivated by two instinctual drives: **Eros (sex drive/life instinct) and Thanatos (aggressive drive/death instinct)**, both from the Id.
        6. Unconscious (Id, Superego) is in **constant conflict with conscious (Ego)**.
        7. Personality shaped by modification of drives at different childhood conflicts (**psychosexual development**).

- **Goal**: Discover unconscious causes to bring them into conscious awareness.
- **Main Headings**: Structure of personality, Dynamics of personality, Development of personality.

- **1.2.1 Structure of Personality**

  - **Two Models**:
    1. **1.2.2 Topographical Model (States of Consciousness)**:
       1. **Conscious**: Whatever one is thinking about at the moment (immediate experiences, short and limited aspect).
       2. **Subconscious/Preconscious**: Stored memories not currently in thought but can be recalled (e.g., what you ate for breakfast). Desires, wishes, feelings that are not currently conscious but can be recalled with effort.
       3. **Unconscious**: Mental elements of which we are unaware. Includes material never conscious, or repressed anxiety-causing material (hostile feelings, sexual cravings, fears). Not directly accessible voluntarily; requires psychoanalyst to uncover.
       4. **Metaphor**: **Iceberg**: Only 10% visible (conscious); 10-15% preconscious; 75-80% unconscious.
    2. **1.3 Dynamic or Structural Model**: Mental map involving three regions of mental activity, constantly in conflict.
       1. **Id**: Present at birth, **totally unconscious**. Deals with **immediate gratification of primitive needs, sexual desires, and aggressive impulses**. Governed by the **pleasure principle**, demands satisfaction without regard for reality or consequences.
       2. **Ego**: Develops in response to reality's limitations. Involves perception, reasoning, learning, interaction with world. Governed by the **reality principle**, finding realistic ways to satisfy Id's demands, mediating between Id and external world to maximize pleasure and minimize pain. Spans all three levels of consciousness.
       3. **Superego**: Develops from **internalizing parental moral values** (ideal behavior, right/wrong). Two aspects: **Ego-ideal** (ideal behavior) and **Conscience** (right/wrong). Deals with ideals and societal demands. Responsible for **guilt feelings** and punishment if one falls short of norms. Spans all three levels of consciousness.

- **1.3.1 Dynamics of Personality**

  - Human organism is a complex system using **physiological energy** (physical activities) and **psychic energy** (psychological work: planning, thinking). Id is contact point for both.
  - **Instincts**: Ultimate cause of all behavior.
    1. **Eros (Life/Love Instinct)**: Establishes and preserves unity through relationships.

2. **Thanatos (Death/Destructive Instinct)**: Undoes connections and unity.
3. **Libido**: Main source of psychic energy, from Eros and Thanatos.

- **Anxiety**: Arises from realistic external sources and internal conflict (e.g., Id desires something Ego/Superego disagrees with).
- **1.3.1.1 Defense Mechanisms**: Ego's unconscious ways to deal with anxiety.
    1. **Denial**: Denies source of anxiety exists (e.g., "I didn't fail, it's a mistake"). Often seen in daydreams/fantasies.
    2. **Repression**: Banishes old, bad memories or current threatening thoughts/desires from consciousness.
    3. **Regression**: Retreating to an earlier, less mature stage of development when stressed (e.g., oral personality smokes more under stress).
    4. **Reaction Formation**: Doing or thinking the opposite of an unwanted impulse; often excessive behavior (e.g., angry person being overly kind).
    5. **Projection**: Ascribing unwanted impulses to someone else (e.g., unfaithful husband suspects wife).
    6. **Rationalisation**: Finding a rational explanation for wrong actions (e.g., failed exam due to "bad questions").
    7. **Intellectualisation**: Turning feelings into thoughts; focusing intellectually to avoid emotions (e.g., becoming an expert on a partner's cancer instead of dealing with grief).
    8. **Displacement**: Moving an impulse from one object to another (e.g., angry with boss, yells at partner).
    9. **Sublimation**: Transforming impulses into something constructive; most adaptive (e.g., chopping wood when angry). Freud believed it led to civilization's greatest achievements.

- **1.3.2 Development of Personality (Psychosexual Stages)**

    - Human development passes through stages based on different ways of obtaining bodily pleasure.
    - **Predetermined sequence**: Successful completion leads to healthy personality; failure leads to unhealthy personality (fixation or regression). Adult personality characteristics determined by experiences in each stage.
    - **Fixation**: Getting "stuck" at a particular stage.
    - **Regression**: Retreating to an earlier stage when things go badly later.
    - **Stages**:
        1. **Oral Stage (Birth to 18 months)**: Pleasure focused on **oral pleasures (sucking)**.
            1. **Fixation**: Oral personality (preoccupation with oral activities - smoking, drinking, overeating, nail-biting). Can be overly dependent, gullible, followers, or pessimistic and aggressive.
        2. **Anal Stage (18 months to three years)**: Coincides with **toilet training**. Pleasure focus on **eliminating and retaining feces**. Marked by conflicts with parents about compliance/defiance.

1. **Fixation**: Anal retentive (obsession with cleanliness, perfection, control) or anal expulsive (messy, disorganized).

3. **Phallic Stage (ages three to six)**: Pleasure zone switches to **genitals**. Children discriminate sex roles.
    1. **Oedipus Complex (boys)**: Unconscious sexual desires for mother, sees father as competitor. Fear of castration leads to identification with father, developing masculine traits and repressing desires.
    2. **Electra Complex (girls)**: (Termed by later psychoanalysts, Freud disagreed) Unconscious sexual attraction to father.
    3. **Fixation**: Sexual deviancies (overindulgence/avoidance), weak/confused sexual identity.
4. **Latency Stage (age six to puberty)**: Libido is dormant, sexual urges repressed. Drives channeled into socially acceptable substitutes (school, hobbies, friendships).
5. **Genital Stage (puberty onward)**: Sexual urges reawakened, directed onto opposite-sex peers. Primary focus is the genitals. Sexual desire blends with affection, adult roles assumed.

- **1.3.3 Evaluation of Freud's Theory**

    - **Merits**:
        1. **Complete theory of personality**, explains behavior.
        2. Emphasizes **unconscious and early childhood experiences**.
        3. Emphasizes **dynamic nature of behavior**.
        4. Emphasizes **defense mechanisms**, stimulated further research.
        5. Led to serious interest in **psychological treatment of mental disorders**.
    - **Demerits**:
        1. **Lacks empirical evidence**, relies too heavily on therapeutic achievements; clinical data flawed/inaccurate.
        2. **Techniques criticized** (dream interpretation, free association).
        3. **Not a science**: Many principles inaccurate.
        4. **Poorly designed concepts** (e.g., "psychic energy" - what is it?).
        5. **Lack of scientific proof**.
        6. **Role of environment overlooked**.
        7. **Over-emphasis on sexual drive**.
        8. **Pessimistic psychic determinism**: No free will?.
- **1.4 Karen Horney: Social Foundation of Personality**

    - **Background**: Criticized Freud, especially **penis envy** (claimed it was envy of men's power; womb envy occurs in men). Desexualized **Oedipal complex** (result of anxiety from disturbed parent-child relationship). Pioneer in **feminine psychiatry**.

    - **Approach**: Reformulated Freudian thought, presented a **holistic, humanistic perspective** emphasizing **cultural and social influences**, human growth, and **self-actualization**.
    - **Main Headings**: Basic Anxiety, Neurotic Needs, Measures to cope with anxiety, Theory of the Self.
- **1.4.1 Basic Anxiety**:

    - A child's feeling of being **isolated and helpless in a potentially hostile world**.
    - Caused by **adverse environmental factors** (termed **basic evil**): domination, erratic behavior, lack of respect for needs, lack of guidance, disparaging attitudes, too much/too little admiration, lack of warmth, parental disagreements, too much/too little responsibility, overprotection, isolation, injustice, discrimination, unkept promises, hostile atmosphere.
    - Basic evil provokes **resentment/basic hostility**, creating a conflict for the child.
- **1.4.2 Neurotic Needs**:

    - **Ten particular patterns** observed in clinical experience. Based on universal needs, but distorted (unrealistic, unreasonable, indiscriminate, intense anxiety if not met).
    - **Examples**:
        1. Need for affection and approval (indiscriminate pleasing).
        2. Need for a partner (takes over one's life, love solves all problems).
        3. Need to restrict one's life to narrow borders (undemanding, inconspicuous).
        4. Need for power (control over others, facade of omnipotence, contempt for weak).
        5. Need to exploit others (manipulation, belief people are for use).
        6. Need for social recognition or prestige (overwhelmed by appearances/popularity).
        7. Need for personal admiration (desperate for importance, fear of being thought nobodies).
        8. Need for personal achievement (obsessed with being number one, devaluing others).
        9. Need for self-sufficiency and independence (shouldn't need anybody, reluctant to commit).
        10. Need for perfection and unassailability (driven to be perfect, scared of flaws, needs control).
    - **Coping Strategies (Clusters of Neurotic Needs)**:
        1. **Compliance (Moving-Toward / Self-Effacing Solution)**: Child faces parental indifference, fears helplessness/abandonment (basic anxiety). Includes needs 1-3 (affection/approval, partner, restrict life).
        2. **Aggression (Moving-Against / Expansive Solution)**: First reaction to parental indifference is anger (basic hostility). Includes needs 4-8 (power, exploit, social recognition, personal admiration, personal achievement).

3. **Withdrawal (Moving-Away-From / Resigning Solution)**: When compliance/aggression fail, child becomes self-sufficient. Includes needs 9-10 (self-sufficiency/independence, perfection/unassailability).

- **1.4.3 Theory of the Self**:
    - Shared Maslow's view of **self-actualization** as a striving goal. Self is the core of one's being and potential. Accurate self-conception allows one to realize potential.
    - **Two Views of Self**:
        1. **Real Self**: Who and what we actually are; potential for growth, happiness, willpower.
        2. **Ideal Self**: Type of person we feel we should be. Used as a model to develop real self's potential.
    - **Neurotic Person's Self**: Split between an idealised self and a despised "real" self. Leads to feeling flawed, not living up to unrealistic goals. Oscillates between "fallacious perfection" and self-hate.
    - **"Tyranny of the Should" and "Search for Glory"**: Neurotic's impossible demands on self (e.g., compliant: "I should be sweet"; aggressive: "I should be powerful"; withdrawing: "I should be independent"). Alienates neurotics from their true core, preventing actualization.
- **1.4.4 Evaluation of Horney's Theory**:
    - **Merits**: Formed **Neo-Freudian Discipline** with Adler. Influential for self-psychologists, humanists, cognitive therapists, feminists, existentialists. Shifted emphasis to cultural/social influences.
    - **Limitations**: Primarily **limited to neurotics**, doesn't fully address psychotics or truly healthy people.
- **1.5 Sullivan's Theory of Personality (Interpersonal Theory of Psychiatry)**
    - **Core Idea**: Psychiatry is the **study of what goes on between people** (interpersonal relations). Contrasts with Freud's focus on internal drives.
    - **Personality**: A **hypothetical entity, cannot be observed/studied apart from interpersonal situations**. Known only through interpersonal interactions. Unit of study is the **interpersonal situation**, not individual person.
    - **Main Headings**: Dynamics of personality, Enduring aspects of personality, Developmental epochs.
- **1.5.1 Dynamics of Personality**:
    - **Energy System**: Personality conceptualized as an energy system. Energy exists as:
        1. **Tension**: Potentiality for action (divided into needs and anxiety).
        2. **Energy Transformations**: The actions themselves.

- **Needs**: Relate to general well-being or specific zones (mouth, genitals). Can be physiological (food, oxygen) or interpersonal (tenderness, intimacy). Conjunctive, call for specific actions to reduce them.
- **Anxiety**: **Chief disruptive force in interpersonal relations**. Disjunctive, calls for no consistent actions for relief. Infants learn anxiety through empathic relationship with mother.
- **Euphoria**: Complete absence of anxiety and other tensions.
- **Levels of Cognition (Ways of Perceiving Things)**:
    1. **Prototaxic Level**: Primitive experiences of infants; impossible to put into words or communicate.
    2. **Parataxic Level**: Prelogical experiences; impossible to communicate accurately. Includes erroneous assumptions about cause and effect (**parataxic distortions**).
    3. **Syntaxic Level**: Experiences that can be **accurately communicated** to others. Children capable of syntaxic language around 12-18 months. Dominant in normal adult life.

- **1.5.2 Enduring Aspects of Personality**:

    - **1.5.2.1 Dynamism**: Term equivalent to **traits**; refers to a **typical pattern of behavior**.
        1. **Two types**: Related to specific body zones (satisfaction of needs like hunger) or related to tensions.
        2. **Tension-related subtypes**:
            1. **Disjunctive Dynamism**: **Malevolence** (feeling of living among enemies); difficulty giving/receiving tenderness.
            2. **Conjunctive Dynamism**: **Intimacy** (close personal relationship between two equal people); facilitates interpersonal development, decreases anxiety/loneliness.
            3. **Isolating Dynamism**: **Lust** (self-centered need, satisfied without intimate relationship).
    - **1.5.2.2 Self-System**: Most inclusive dynamism. Pattern of behaviors that **protects against anxiety** and maintains interpersonal security. Tends to **stifle personality change**.
        1. **Security Operations**: Behaviors to reduce interpersonal tensions.
            1. **Dissociation**: Blocking experiences from awareness.
            2. **Selective Inattention**: Blocking only certain experiences from awareness.
    - **1.5.2.3 Personifications**: Mental images of ourselves and others developed through social interactions and selective attention/inattention. Can lead to misperception of reality.
        1. **Three Basic Ways We See Ourselves**:
            1. **The Bad-Me**: Aspects considered negative, hidden from others/self. Anxiety from recognizing this part.

2. **The Good-Me**: Everything we like about ourselves; shared with others, produces no anxiety.
3. **The Not-Me**: Things so anxiety-provoking they cannot be considered part of self; pushed deep into unconscious to avoid anxiety.

- **1.5.2.4 Developmental Epochs**:
    - Sullivan believed childhood experiences determine adult personality, but also that personality can develop in adolescence and adulthood.
    - **Stages**:
        1. **Infancy (Birth to 1 year)**: Child begins development, less emphasis than Freud.
        2. **Childhood (1 year – 5 years)**: Development of speech, improved communication.
        3. **Juvenile ages (6-8 years)**: Need for playmates, beginning of healthy socialization.
        4. **Preadolescence (9-12 years)**: Major focus on ability to form **close relationship with a peer** (assists in feeling worthy/likable).
        5. **Early Adolescence (13-17 years)**: Need for friendship changes to **need for sexual expression**. Self-worth linked to sexual attractiveness/acceptance.
        6. **Late Adolescence (18-22/23 years)**: Need for friendship and sexual expression combine; **long-term relationship** becomes primary focus. Conflicts with parental control, skewed perception of self/world due to overuse of selective inattention.
        7. **Adulthood (23 years and above)**: Struggles with financial security, career, family. Success in earlier stages makes adult relationships and socialization easier.
- **1.5.2.5 Evaluation of Sullivan's Theory**:
    - **Merits**: Insights into importance of interpersonal relations.
    - **Limitations**: Lost popularity. Rates low in falsifiability, low in research generation, average in organizing knowledge/guiding action, average in self-consistency, low in parsimony. High on social influences, low on biological; high on unconscious, average on free choice/optimism/causality, low on uniqueness.

Unit 2: Social Cognitive Theory of Personality (Bandura)

- **2.2 Social Cognitive Theory**
    - **Basis**: Social learning theory based on ideas of **learned behavior through environmental interaction**, but **individual person (cognition) is just as important** as environment.

    - **Determinants**: Explains behavior as continuous reciprocal interaction between **cognitive, behavioral, and environmental determinants**. These factors are reciprocal, not static or independent.
    - **Key Learning Process**: People learn by **observing others (vicarious learning)**.
- **2.2.1 Main Tenets of Social Cognitive Theory**:
    - Learning occurs by **observing others (vicarious learning)**. Behavior is not always applied even if learned; choice based on perceived/actual consequences.
    - More likely to follow **behaviors modeled by someone identifiable** (commonality, emotional attachments).
    - **Self-efficacy** directly affects learning ability.
- **2.3 Albert Bandura's Social Learning Theory (now Social Cognitive Theory)**
    - **Premise**: Human behavior is largely **acquired**, and learning principles account for its development/maintenance.
    - **Shift from earlier learning theories**: Focus on **social context** of behavior.
    - **Cognitive Focus**: Differentiates Bandura from Skinner; focuses on **motivational factors and self-regulatory mechanisms** contributing to behavior, not just environmental factors.
    - **Main Headings**: Reciprocal determinism, Self-system, Principles of observational learning.
- **2.3.1 Reciprocal Determinism**:
    - Rejects one-sided determinism (behavior shaped only by environment or internal dispositions).
    - **Triadic Reciprocal Causation**: **Behavior (B), personal factors (P), and environmental influences (E) all operate as interacting determinants that influence each other bidirectionally**.
    - **Interactions**:
        - **P ↔ B (Personal factors ↔ Behavior)**: Thoughts, beliefs, feelings shape behavior.
        - **E ↔ P (Environment ↔ Personal factors)**: Human expectations, beliefs, emotional bents, cognitive competencies developed/modified by social influences.
        - **B ↔ E (Behavior ↔ Environment)**: Behavior alters environmental conditions, which in turn alters behavior. People are products and producers of their environment (select/create situations).
    - Complete behavior analysis requires considering all three sets of influence.
- **2.3.2 Self-system**:
    - The "starting point" for reciprocal determinism.

    - Not a psychic agent, but **cognitive structures providing reference mechanisms and functions for perception, evaluation, and regulation of behavior**.
    - **Components of Self-regulation**:
        - **Self-observation**: Monitoring one's own behavior.
        - **Judgment**: Comparing observed behavior with a standard (e.g., rules, personal goals, competition).
        - **Self-response**: Rewarding or punishing oneself based on judgment (e.g., pride or shame).
    - **Self-efficacy**: A very important concept related to self-regulation.
        - **Definition**: "**Belief in one's capabilities to organise and execute the courses of action required to manage prospective situations**" (Bandura, 1995).
        - **Role**: Impacts how goals, tasks, challenges are approached.
        - **Characteristics**:
            - **Strong Self-Efficacy**: View problems as tasks to master, deeper interest, stronger commitment, quicker recovery from setbacks.
            - **Weak Self-Efficacy**: Avoid challenging tasks, believe tasks are beyond capabilities, focus on failings/negative outcomes, quickly lose confidence.
        - **Sources of Self-Efficacy**: Develops from childhood, continues evolving.
            - **Mastery Experiences**: **Most effective way**; successfully performing a task strengthens efficacy; failure weakens it.
            - **Social Modeling (Vicarious Experiences)**: Observing others similar to oneself succeed raises belief in own capabilities for comparable activities.
            - **Social Persuasion**: Being persuaded by others that one has skills to succeed; verbal encouragement helps overcome self-doubt.
            - **Psychological Responses**: Own emotional reactions, moods, stress levels impact perception of abilities (e.g., nervousness before public speaking creates weak self-efficacy).
- **2.3.3 Principles of Observational Learning / Modeling**:

    - Emphasizes social origins of behavior and cognitive thought processes.
    - **Learning can occur without direct reinforcement**, simply through observation of models. Traditional principles of learning are more relevant to performance than acquisition.
    - **Bobo Doll Experiment**: Children exposed to film of adult beating Bobo doll imitated the aggressive behavior precisely without prior reward. Demonstrated **observational learning / modeling**.
    - **Steps in Modeling Process**:
        - **Attentional Processes**: Must be paying attention. Influenced by model characteristics (colorful, attractive, prestigious, competent, similar to self) and observer characteristics (sensory capacities, motivation, arousal).

        - **Retentional Processes**: Ability to store information. Encoded as mental images or verbal descriptions for later reproduction.
        - **Reproduction Processes**: Ability to perform the observed behavior. Improves with practice (even imagined).
        - **Motivational Processes**: Must be motivated to imitate.
            - **Positive Motivators**: Past reinforcement, promised reinforcements (incentives), vicarious reinforcement (seeing model reinforced).
            - **Negative Motivators**: Past punishment, promised punishment (threats), vicarious punishment.
            - **Note**: Punishment is less effective than reinforcement, tends to "backfire".
- **2.3.4 Vicarious Learning**:
    - Closely related to observational learning.
    - **Definition**: **Learning from other people's behavior**. Individuals witness observed behaviors and reproduce them.
    - **Benefit**: Individuals refrain from making mistakes and perform behaviors better by observing successful completion by others.
    - **Significance**: Crucial for human development and survival; avoids trial-and-error. Symbolic modeling (verbal/pictorial) allows new ways of thinking/behaving to be transmitted to many people simultaneously. Influences conceptions of social reality without direct experience.
- **2.3.5 Evaluation of Bandura's Theory**:
    - **Merits**:
        - **Powerful predictions**, generated useful applications in many areas.
        - **Well-grounded in research**, terms are clearly defined, lending to empirical research.
        - **High applied value**.
    - **Limitations**:
        - Behavior found to be **more consistent** than theory argues (focuses heavily on situation).
        - **Lacks attention to biological/hormonal processes**.
        - **Not unified**: Concepts like observational learning and self-efficacy highly researched, but little explanation of relationship among concepts.

Unit 3: Learning Theory of Personality (Pavlov and Skinner)

- **3.0 Introduction**
    - **Learning Theory of Personality**: Emphasizes **observable behavior, stimulus-response relationships, and impact of learning**.
    - **Behaviorist Position**: Personality is a **collection of learned behavior patterns**. Does not prioritize internal causes of behavior.

    - **Acquisition**: Personality acquired through classical/operant conditioning, observational learning, reinforcement, extinction, generalization, discrimination.
- **3.2 Pavlov: Learning Theory of Personality**

    - **Background**: Physiologist, behaviorist.conditioned Response (UCR)**: Natural, unlearned response to UCS (e.g., Salivation to meat powder).
        - **Conditioned Stimulus (CS)**: Previously neutral stimulus that, after being paired with UCS, comes to elicit a response (e.g., Bell).
        - **Conditioned Response (CR)**: Learned response to the CS (e.g., Salivation to bell).
        - **Pairing**: CS (bell) presented briefly, followed by UCS (meat powder); repeated pairings lead CS to evoke CR.
        - **Higher-order conditioning**: CS can serve as basis for further conditioning (e.g., light paired with bell also elicits salivation).
- **3.2.2 Principles of Classical Conditioning**:

    - **3.2.2.1 Acquisition**: Factors influencing CS's ability to elicit CR:
        - **Number of Pairings**: More pairings increase strength of CR.
        - **Interval between CS and UCS**: Optimal interval for many responses is 0.50 seconds. Some cases (e.g., taste aversion) can be longer (over an hour).
        - **Applications**: Explains acquisition of irrational fears (phobias), sexual hang-ups (fetish), prejudice, hostile feelings.
    - **3.2.2.2 Generalisation and Discrimination**:
        - **Stimulus Generalisation**: Organism responds to stimuli similar to the conditioned stimulus. Plays an adaptive role (e.g., fear response to different bee/wasp sounds).
        - **Stimulus Discrimination**: Ability to discriminate between two stimuli when one is consistently followed by UCS, and the other is not.
        - **Experimental Neurosis**: When discrimination limits are exceeded (e.g., dog unable to distinguish circle from almost-round ellipse after training), extreme stress and abnormal behavior result. Attributed to disturbance in balance between excitatory and inhibitory processes in nervous system.
    - **3.2.2.3 Extinction and Spontaneous Recovery**:
        - **Extinction**: CS repeatedly presented without UCS; CR gradually decreases and fades. Important for normal personality to get rid of useless reactions.
        - **Spontaneous Recovery**: Extinguished CS presented later; capacity to evoke CR reappears.
- **3.2.3 Principles of Behaviour Modification (Classical Conditioning Applications)**:

    - Used in **treatment of neurosis and phobias** by eliminating symptoms via reinforcement of extinction.
    - **Flooding**: Therapeutic technique for phobias, relies on extinction.

    - **Systematic Desensitisation**: Successfully deals with maladaptive behaviors (examination anxiety, phobias, stuttering, depression) based on extinction principles.
    - **3.2.4 Process of Behaviour Modification**:
        - **Counter-conditioning / Aversion Therapy**: Pairing unpleasant effect (UCS, e.g., nausea-inducing drug) with conditioned stimulus (e.g., taste of alcohol/nicotine) to create negative aversion. Successfully used for addictions.
- **3.2.5 Evaluation of Pavlov's Theory**:
    - **Merits**: Explains development/change of aspects of personality, applicable to psychopathologies.
    - **Limitations**: Unable to explain total personality. Principles drawn from animal experiments, questionable applicability to humans.
- **3.3 B. F. Skinner: Learning Theory of Personality**
    - **Background**: Theory emerged from **laboratory settings**, studying individual subjects in controlled conditions. Focused on **observable behavior and environmental determinants**, rejected internal sources.
    - **Study of Personality**: Based on systematic evaluation of genetic and idiosyncratic learning history; discovering relationship between organism's behavior and reinforcing consequences.
    - **Assumptions**: Behavior is **lawful, predictable, and controllable**.
- **3.3.1 Operant Behaviour**:
    - **Respondent Behaviors**: Elicited by identifiable environmental stimuli; involuntary, automatic (e.g., pupil constriction, salivation). Usually not learned at simple level.
    - **Operant Behaviors**: Not caused by specific environmental stimuli; stimuli difficult to identify [41 * **Positive Reinforcement**: Adding something pleasant to increase behavior likelihood. * **Negative Reinforcement**: Removing something unpleasant to increase behavior likelihood.
        - **Extinction**: Behavior no longer followed by reinforcing stimulus, leading to decreased probability of future occurrence.
        - **Spontaneous Recovery**: Return of lever-pressing behavior if reinforcement is restored, much quicker than original learning.
- **3.3.2 Schedule of Reinforcement**: How reinforcement is delivered.
    - **Continuous Reinforcement**: Reinforcement given every time behavior occurs.
    - **Partial Reinforcement (Intermittent)**: Reinforcement not given every time.
        - **Fixed Ratio (FR)**: Reinforcement after a fixed number of responses (e.g., every 3 presses).
        - **Fixed Interval (FI)**: Reinforcement for first response after a fixed time period (e.g., every 20 seconds). Rats "pace" themselves.

        - **Variable Ratio (VR)**: Number of responses for reinforcement changes each time (e.g., 3, then 10, then 1 press). **Very resistant to extinction**.
        - **Variable Interval (VI)**: Time period for reinforcement changes each time (e.g., 20, then 5, then 35 seconds). No "pacing," also **very resistant to extinction**.
- **3.3.3 Aversive Stimuli (Punishment)**:
    - **Punishment**: Behavior followed by an aversive stimulus, resulting in decreased probability of behavior. (e.g., shocking a rat, spanking a child).
    - **Negative Reinforcement vs. Punishment**: Removing an already active aversive stimulus after a behavior is negative reinforcement, which increases behavior (e.g., turning off shock when rat stands).
    - **Skinner's View on Aversive Stimuli**: Does not "approve" of them because they **do not work well**. They suppress, not remove, the behavior, which can resurface or become more resistant to extinction (variable schedule).
- **3.3.4 Secondary Reinforcement**:
    - A neutral stimulus presented at the time of delivering primary reinforcement acquires reinforcing ability (e.g., clicker sound in Skinner box).
    - **Importance in Human Behavior**: Much of human behavior relies on secondary reinforcement. **Money** is the most common example, acquiring value by being paired with primary reinforcers.
- **3.3.5 Successive Approximation or Shaping**:
    - Method for achieving **more complex behaviors**.
    - Involves **reinforcing a behavior only vaguely similar to the desired one**, then reinforcing closer variations until target behavior is performed. (e.g., teaching animals extraordinary tricks).
- **3.3.6 Superstitious Behaviour**:
    - **Superstitious Conditioning**: Conditioning where there is **no causal relationship between response and reinforcer**. Reinforcement occurs by chance, but individual believes their response caused it.
    - **Examples**: Rain-making dances reinforced by chance rain. Attributing failure to a cat crossing one's path.
- **3.3.7 Abnormal Behaviour**:
    - Skinner believed his framework was sufficient to explain abnormal behavior, rejecting concepts like repressed wishes or identity crises.
    - Assumed to follow **same principles of development as normal behavior**.
    - **Treatment Goal**: Replace abnormal with normal behavior by manipulating environment using operant/respondent conditioning techniques.
        - **Extinguish undesirable variations.

        - Useful **therapeutic applications** (behavior problems, e.g., token economy).
    - **Weaknesses**:
        - Explains specific behaviors, but **not a comprehensive theory of personality**; "personality" concept often missing.
        - **Ignores biological factors** and individual differences present from birth.
        - **Lacks in-depth case studies**; no comprehensive personality assessment tests developed from this perspective.
        - **Unable to fully explain complex human behaviors** like language (Chomsky's critique: how do children form novel sentences, cross-cultural similarity?).
        - **Questionable applicability of animal behavior principles to complex human behavior** (Boulding, 1984). Requires more human participant experiments for validity.

Unit 4: Humanistic and Self Theory (Maslow and Rogers)

- **4.2 Humanistic and Self Theories of Personality**

    - **Definition**: Focus on the **entire person**; believe persons are **inherently good with unique attributes for greatness**. Labeled humanistic, organismic, or person-centered.
    - **Origin**: Response to perceived limitations of Psychodynamic theories, especially psychoanalysis.
    - **Distinguishing Factors**:
        - Emphasis on **subjective meaning** of behavior.
        - Rejection of **determinism**.
        - Concern for **positive growth** rather than pathology.
        - Argue individual is capable of understanding own behavior; science relies on **intersubjective verification** (agreement among observers).
    - **Main Aim**: Provide concepts/methods for stimulating **learning, growth, development** in individuals/society, enhancing well-being and quality of life.
    - **"Third Force"**: Maslow coined term to describe Humanistic Approach, differentiating it from Psychodynamic and Behaviorist approaches. Focuses on helping people develop better, become more competent, aware, happier, reaching "optimal" mental health.
    - *** **Key Figure**: Founder of Humanistic Approach. Influenced by Kurt Goldstein's idea of self-actualization.
    - **Unique Contribution**: Preoccupation with **healthy people** rather than sick ones; studies of these two groups generate different theories.
    - **Core Belief**: Humans strive for an upper level of capabilities, seek frontiers of creativity/consciousness/wisdom ("fully functioning person," "healthy personality," "self-actualizing person"). Not pushed by mechanical forces (behaviorism) or unconscious impulses (psychoanalysis).

    - **Main Headings**: Hierarchy of needs, Deficit needs, Growth needs, Self-actualizers.
- **4.3.1 Hierarchy of Needs**:
    - **Theory of Human Motivation**: Needs arranged in a hierarchy.
    - **Prepotency**: Lower needs are more dominating; higher-order needs emerge **only when lower-level needs are satisfied**.
    - **Two Categories**:
        - **Deficiency Needs (D-needs)**: First four levels; lack of satisfaction causes a deficiency that motivates people. Operate on **homeostasis principle** (e.g., hunger when body lacks substance). People move through these levels like stages in early life, can "regress" under stress, or "fixate" if problems in development.
            - **Physiological Needs (lowest)**: Basic survival (air, food, water, sleep). Most basic and instinctive.
            - **Safety Needs**: Security and safety (steady employment, health insurance, safe neighborhoods, shelter). Important for survival, less demanding than physiological.
            - **Belongingness Needs**: Belonging, love, affection, companionship, acceptance (friendships, family, social/community groups). Less basic than physiological/security.
            - **Esteem Needs**: Recognition from others, confidence, achievement, self-esteem.
                - **desire for personal growth** and to become all one is capable of. Involves continuous desire to fulfill potentials, "be all you can be". Requires lower needs to be substantially met.
            - **Definition**: "What a man can be, he must be". Desire to become more and more what one is. Specific to individuals (e.g., ideal parent, athlete, artist).
            - **Achieving self-actualization**: Requires achieving and mastering previous needs.
- **4.3.4 Characteristics of Self-actualisers (Based on Biographical Analysis)**:
    - **Reality-centered**: Differentiate fake from real.
    - **Problem-centered**: Treat difficulties as problems demanding solutions.
    - **Different perception of means and ends**: Means can be ends themselves; journey often more important than end.
    - **Relating to others**: Enjoy solitude, deeper personal relations with few, rather than shallow relations
    - **Spontaneity and simplicity**: Prefer being themselves over pretentiousness.
    - **Humility and respect towards others** (democratic value).
    - **Human kinship**: Social interest, compassion, humanity.
    - **Strong ethical behaviors**.

    - **Spiritual but not conventionally religious**.
    - **Freshness of appreciation**: Ability to see ordinary things with wonder.
    - **Creative, inventive, original**.apathologies** (depression, despair, disgust, alienation, cynicism).
- **4.3.5 Evaluation of Maslow's Theory**:

    - **Merits**: Inspirational figure. Brought human being back into psychology. Unique focus on healthy people.
    - **Limitations**:
        - **Methodology criticized**: Small sample, self-declared self-actualizing individuals, qualitative biographical analysis.
        - **Constraints on self-actualization**: Limits it to ~2% of human species, rarely achieved by young (contrary to Goldstein/Rogers who saw it in all living creatures/babies).
        - Assumption that lower needs must be met first: Many great artists/authors suffered poverty, bad upbringing, neuroses, depression while achieving greatness.
- **4.4 Carl Rogers's Theory of Personality (Self-Theory / Person-Centered Theory)**

    - **Background**: Influential therapist. Theory grew out of clinical work.
    - **Approach**:2. **Conditions for healthy growth**: Therapist provides **empathy, openness, and unconditional positive regard** (person-centered therapy, non-directive, therapist as "mirror").
- **4.4.1 Enduring Aspects of Personality**:

    - **4.4.1.1 The Organism**:
        - **Locus of all experience**, including everything potentially available to awareness.
        - **Phenomenal Field**: The totality of experience; individual's frame of reference, known only to that person (or through empathetic experience,'s picture of him/herself.
        - **Real Self**: The "you" that, if all goes well, you will become; created through the **actualizing tendency**.
        - **Ideal Self**: What the person would like to be; often out of reach, a standard that cannot be met. An ideal imposed by society's demands, not something to strive for.
        - **Congruence**: For happiness and self-actualization, public and private selves must be as similar as possible (, potentially malfunctioning.
            - **Defense Mechanisms**:
                - **Distortion**: Perceives threat to self-concept and distorts perception to fit self-concept. Reduces consciousness of threat, not threat itself.
                - **Denial**: Blocks experiences from awareness.

        - Moderate incongruence leads to neurotic state, rigid self-structure. Severe incongruence can lead to breakdown of defenses, disorganization of personality, bizarre/irrational behavior.
        - Psychological maladjust**: Directional, constructive, present in all living things. Can be suppressed but not destroyed without destroying organism.
    - **Encompasses all motivations**: Tension/need/drive reductions, creative and pleasure-seeking tendencies.
    - **Selective**: Pays attention to environmental aspects that move person constructively toward fulfillment/wholeness.
    - **Single goal of life**: To become self-actualized.
- **4.4.3 The Development of Self**:

    - **No Stage Theory**: Unlike Freud, Sullivan, Erikson, Rogers did not propose specific stages.
    - **Emphasis**: Importance of **congruence between person's self and experiences** in personality development.
    - **Psychological Health**: Realistic self-concept congruent with self.
    - **Incongruence Impact**: If self-concept doesn't match actual experience (e.g., taught "nice people never get angry" but then feel angry), leads to maladjustment and anxiety. Large self-experience discrepancy can lead to defensive
    - **Parental Guidance (Rogers's 3 points)**:
        - Child's feelings must be **recognized and accepted**.
        - Avoid threatening child with **loss of love**.
        - Hostile behavior must be **clearly and unmistakably rejected and prevented**.
- **4.4.4 Evaluation of Rogers's Theory**:

    - **Merits**: Wide application (psychotherapy, counseling, organizations). Encouraged humane/ethical treatment of persons, approaching psychology as human science.
    - **Limitations**:
        - **"Naïve phenomenology"**: Psychologists impose views based on client's self-reports (which can lack credibility).
        - **Ignores unconscious determinants** of behavior.
        - Deals only with **surface issues**, doesn't explore deeper areas.

Block 3: Theories of Personality

Unit 1: Gordon Allport: A Dispositional Theory of Personality

- **Introduction to Allport's Theory**
    - Allport believed the basic principle of behavior is its **continuous flow**.
    - His concepts emphasize **motivation**, explaining "what makes a person 'go'".
    - Personality has a **'constant portion' (trait)** and a **'variable portion' (functional autonomy)**, both of which are motivational.
- **Definition of Personality**
    - Personality is the **dynamic organization within the individual** of **psychophysical systems** that **determine his unique adjustment to his environment**.
    - "Dynamic organization" means personality is **constantly developing and changing**, with a central organization holding components together.
    - "Psychophysical systems" implies personality is a real phenomenon composed of **mind and body elements fused into a 'personality unity'**.
    - "Unique adjustment" signifies the **uniqueness of each person**; no two people are alike.
    - Personality expresses itself in **virtually all observable human actions**.
    - Allport distinguishes personality from **character** (moral evaluation of behavior) and **temperament** (biologically/physiologically linked dispositions, like heredity, intelligence, physique, which are raw materials for personality).
- **Concept of Trait and Personal Dispositions**
    - A **trait** is a **neuropsychic structure** with the capacity to render many stimuli functionally equivalent and to initiate and guide meaningfully consistent adaptive and expressive behavior.
    - Simply, a trait is a **predisposition to act in the same way in a wide range of situations**.
        1. *Example:* A shy person tends to be quiet and reserved in various situations, like a classroom or cafeteria.
    - Traits make many stimuli and responses **functionally equivalent**.
    - **Eight Basic Characteristics of Traits (Allport, 1966)**:
        1. A trait has **more than nominal existence**; it's a real part of everyone's existence.
            - *Example:* A person always telling the truth, even at personal cost, reflects a real trait.

2. A trait is **more generalized than a habit**. Habits are specific and less generalized. Traits account for relatively **permanent and general features** of behavior.
    - *Example:* Brushing teeth daily is a habit, but many habits like brushing hair, washing clothes, cleaning form the trait of **personal cleanliness**.
3. A trait is **dynamic or determinative in behavior**; it motivates people to express it.
    - *Example:* A sociable student actively seeks parties to express sociability.
4. A trait's existence can be **established empirically** (e.g., repeated actions, case histories, statistical techniques).
5. Traits are **only relatively independent**; they overlap, and personality is a network of overlapping traits.
6. A trait is **not synonymous with moral or social judgment**; personality is distinct from character.
7. A trait can be viewed in light of the **individual personality** or its **distribution in the population**.
    - *Example:* Shyness is unique to a person's life but can also be studied universally with a "shyness scale".
8. **Inconsistent acts or habits do not negate a trait's existence**. People can have contradictory traits, and social situations can be prime movers of behavior.

- **Types of Traits**
    - Allport classified traits into a three-fold, somewhat overlapping category system based on pervasiveness:
        1. **Cardinal Trait:** Extremely pervasive; almost all of a person’s activities can be traced to its influence.
            - *Example:* Referring to someone as "Ghandhian" implies the cardinal disposition of **'non-violent'**.
        2. **Central Trait:** Less pervasive but still generalized dispositions, considered the **building blocks of personality**. Often expressed and readily discernible by others.
            - *Example:* Being **outgoing, sociable**.
        3. **Secondary Trait:** Less conspicuous, generalized, consistent, and relevant. Requires intimate knowledge of a person to discern.
            - *Example:* Food preferences.
    - **Common Traits versus Individual Traits (Personal Dispositions)**
        1. **Common Traits (Dimensional or Nomothetic):** Generalized dispositions to which most people within a given culture can be compared.
            - *Example:* Social attitude, anxiety, value.
        2. **Individual Traits (Personal Dispositions or Morphological Traits):** Characteristics peculiar to the individual that do not permit comparisons

among individuals. These operate uniquely within each person and most accurately pinpoint the organized focus of their life. Obtained from sources like case histories, diaries, letters.

- **The Proprium: Development of Selfhood**
    - **Opportunistic Functioning:** Satisfying biological survival needs; reactive, past-oriented, biological (Allport considered this relatively unimportant for understanding most human behavior).
    - **Propriate Functioning:** Motivates behaviors that express one's unique self; proactive, future-oriented, psychological.
        1. *Example:* Doing something because it truly feels like "you".
    - **Proprium Defined:** Allport's term for the **essential concept of the self**. He sought a more scientific term than "self" but "self" continues to be used.
    - **Proprium from Two Viewpoints:** Phenomenological (what the self experiences as essential, warm, central) and Functional (seven functions).
    - **Seven Functions/Developmental Stages of the Proprium**:
        1. **Sense of Bodily Self:** Awareness of bodily sensations; evolves during the first year of life (e.g., sensations from muscles, tendons).
        2. **Self-Identity:** Continuity of self despite changes; evolves through language, recognizing oneself as distinct and constant (e.g., learning one's name, clothing, toys).
        3. **Sense of Self-Esteem:** Pride in accomplishments; emerges around age three; depends on success in mastering tasks and exploring the environment.
        4. **Sense of Self-Extension:** Self comes to include relevant aspects of the social and physical environment; evolves ages 4-6 (e.g., understanding "mine").
        5. **Self-Image:** Aspirations reflect goals/expectations of significant others; evolves around ages 5-6 (e.g., distinguishing "good me").
        6. **Sense of Self as Rational Coper:** Abstract reasoning and logic applied to solving everyday problems; occurs ages 6-12 (e.g., realizing rational capacity to cope with reality).
        7. **Propriate Striving:** Unified sense of self and planning for long-range goals; core problem of adolescence (career, life goals); requires unified selfhood, emerges in adulthood.
- **Functional Autonomy of Motives**
    - **Definition:** Motives for a certain behavior today are **independent (autonomous) of their origins**. Allport did not believe in looking too much into the past to understand the present.
        1. *Example:* A student studies IT because it was required, but later becomes absorbed for life; the original motive (requirement) is no longer the reason for continuing.
    - **Types of Functional Autonomy**:

1. **Preservative Functional Autonomy:** Refers to **feedback mechanisms in the nervous system** that are neurologically self-maintaining. Characterized by repetitious activity.
    - *Example:* Eating and going to bed at the same time each day.
2. **Propriate Functional Autonomy:** Refers to **acquired interests, values, attitudes, and intentions** of the person. It's the master system of motivation that gives consistency to striving for a congruent self-image and higher maturity/growth. Represents striving for values and goals.

- **The Mature Personality**
    - Emergence of personal maturity is a **continuous, lifelong process of becoming**.
    - Mature person's behavior is **functionally autonomous** and motivated by **conscious processes**. Immature persons are dominated by unconscious, childhood motives.
    - **Six Attributes of a Psychologically Mature Adult**:
        1. **Widely extended sense of self:** Actively participates in work, family, social relationships, hobbies, political/religious issues; gets 'outside' themselves.
        2. **Capacity for warm social interactions:** Shows intimacy (deep love for family/friends) and compassion (tolerates differences, respects human condition).
        3. **Emotional security and self-acceptance:** Positive self-image, tolerates frustrating events/shortcomings without hostility, manages emotions without interfering with others' well-being.
        4. **Realistic perception, skills, and assignments:** Sees things as they are (not as wished), in direct contact with reality, possesses appropriate skills for work, prioritizes tasks over personal desires.
        5. **Self-insight and humor:** Accurate picture of strengths/weaknesses; humor prevents self-glorification and phoniness, ability to laugh at cherished things (including self) and still cherish them.
        6. **Unifying philosophy of life:** Clear, consistent, systematic way of finding meaning; has a value system (deeply held values) that provides a dominant goal or theme, giving purpose to life.
- **Application: The Study of Values**
    - The unifying philosophy of a mature person is founded on **values**, basic convictions about what is important.
    - Allport's "Study of Values" personality test is based on Eduard Spranger's six major value types, found in varying degrees in all people.
    - These values are **deep-level traits**:
        1. **The Theoretical:** Concerned with **discovery of truth**; rational, critical, empirical approach; intellectual; careers in science/philosophy.

2. **The Economic:** Values **usefulness or pragmatism**; highly 'practical,' interested in making money.
3. **The Aesthetic:** Values **form and harmony**; importance given to grace, symmetry, fitness in every experience.
4. **The Social:** Highest value is **love of people**; views theoretical, economic, aesthetic as cold/inhuman; regards love as only suitable relationship.
5. **The Political:** Main interest is **power**; seeks personal power, influence, renown.
6. **The Religious:** Concerned with **understanding the world as a unified whole**; seeks unity and higher meaning in the cosmos.

- The "Study of Values" scale (45 questions, 20 mins) assesses individual differences in the strength of these values; reliable and valid.

Unit 2: Raymond Cattell: A Trait Theory of Personality

- **Introduction and Definition**
  - Cattell's theory explains complex interactions between the **personality system and the sociocultural matrix**.
  - An adequate theory must account for **multiple traits**, their **genetic and environmental determination**, and their interaction.
  - Cattell used an **inductive method** (factor analysis on large data sets) to identify personality factors.
  - For Cattell, personality is "that which **permitted a prediction of what a person will do in a given situation**".
- **The Formula for Personality**
  - Cattell proposed a **specification equation** to predict behavior: **R = f (S, P)**.
    1. **R** refers to the **nature of a person's specific response** (what they do, think, verbalize).
    2. **f** refers to an **unspecified function**.
    3. **S** refers to the **stimulus situation** at a given moment.
    4. **P** refers to the **Personality structure**.
  - This formula means response is a function of **combined traits relevant to the situation**, interacting with situational factors (moods, roles). Each trait is weighted by its relevance (e.g., anxiety trait gets high weight in emotional situations). This shows Cattell's belief that human behavior is **determined and predictable**.
- **Categories of Traits**
  - Traits are **relatively permanent and pervasive tendencies** to respond consistently across time and situations. They are **hypothetical mental structures inferred from behavior**.
  - Cattell (1965, 1978) used **factor analysis** to identify structural elements of personality.

- **Surface Traits versus Source Traits**:
    1. **Surface Trait:** A set of **behavioral characteristics that 'hang together'**. They do not have a unitary basis and are not consistent over time; less value for behavioral accountability.
        - *Example:* Inability to concentrate, indecisiveness, restlessness may cluster to form the surface trait of **neuroticism**.
    2. **Source Trait: Basic, underlying structures** that are the **building blocks of personality**. They represent unitary dimensions that determine consistencies in observed behavior. Exist at a "deeper" level and cause behavior across diverse domains over time.
        - Cattell identified **16 source traits** as the underlying structure of personality: Warmth, Reasoning, Emotional Stability, Dominance, Liveliness, Rule Consciousness, Social Boldness, Sensitivity, Vigilance, Abstractness, Privateness, Apprehension, Openness to Change, Self-reliance, Perfectionism, Tension.
- **Global Traits (Secondary Traits):** Primary traits group into broader global traits.
    1. **Introversion-Extraversion:** Formed from Warmth, Liveliness, Social Boldness, Forthrightness, Affiliative.
    2. **Receptivity or Openness (vs. Tough-Mindedness):** Formed from Sensitivity, Abstractedness, Openness-to-Change, Warmth.
    3. **Anxiety:** Formed from Emotional Stability, Vigilance, Apprehension, Tension, Self-reliance. (Note: Source explicitly mentions anxiety as a global trait formed by primary factors, but only lists the primary factors that *constitute* the extraversion and receptivity global traits. The 16 source traits list includes Emotional Stability, Apprehension, Tension, and Self-reliance which are linked to anxiety in other models, so it's a reasonable inference based on the text structure.)
    4. **Self-Control/Restraint (vs. Impulsivity):** Formed from Rule-Consciousness, Perfectionism, Seriousness (Liveliness-Factor F, but serious is low liveliness), Groundedness (Abstractedness-Factor M, but grounded is low abstractedness).
- **Constitutional versus Environmental-Mold Traits:** Source traits classified by origin:
    1. **Constitutional Traits:** Derive from **biological and physiological conditions**; resistant to change.
        - *Example:* Irritability, depression, anxiety from cocaine recovery due to physiological changes.
    2. **Environmental-Mold Traits:** Determined by **social and physical environment influences**; learned characteristics and behavioral styles imprinted by environment.
        - *Example:* Behaviors differing in rural vs. urban settings.
- **Ability, Temperament, and Dynamic Traits:** Source traits classified by modality of expression:
    1. **Ability Traits:** Determine **skill and effectiveness in pursuing goals**.

        - *Example:* Intelligence, musical aptitude.
    2. **Temperament Traits:** Relate to **emotional and stylistic qualities of behavior**. Cattell sees them as constitutional source traits determining emotionality.
        - *Example:* Working quickly or slowly.
    3. **Dynamic Traits:** Reflect **motivational elements**, activating and directing toward particular goals.
        - *Example:* Ambitious, power-oriented, interested in material possessions.
- **Common versus Unique Traits**:
    1. **Common Trait:** Shared in varying degrees by **all members of the same culture**.
        - *Example:* Self-esteem, intelligence, introversion.
    2. **Unique Trait:** Shared by **few or no other people**; especially seen in interests and attitudes.

- **Role of Heredity and Environment**

    - Cattell devised **Multiple Abstract Variance Analysis (MAVA)** to estimate the degree to which traits are due to genetic or environmental influences.
    - MAVA data (from twin/sibling studies) suggests **65-70% of intelligence and assertiveness variation is genetic**, while conscientiousness and neuroticism have half that genetic influence.
    - Cattell estimates **two-thirds of personality is determined by environmental influences and one-third by heredity**.
    - **Syntality:** Trait dimensions along which **groups can be objectively described**. Cattell studied syntality of religious, school, peer groups, and nations (e.g., size, morale, affluence, industriousness).
- **Measurement of Traits**

    - Cattell drew data from three sources:
        1. **Life Record Data (L-data):** Measurement of behavior in actual, everyday situations (e.g., school performance, peer interactions).
        2. **Self-Rating Questionnaire Data (Q-data):** Person's self-ratings about behavior, feelings, thoughts; reflects introspections; prone to faking.
            - *Example:* **Sixteen Personality Factor Questionnaire (16 PF)** assesses 16 source traits.
        3. **Objective Test Data (OT-data):** Derived from special situations where performance is objectively scored; resistant to faking.
            - *Example:* Rorschach test responses.

Unit 3: Hans Eysenck: A Trait-Type Theory of Personality

- **Introduction and Distinction**

    - Eysenck's theory is a **trait-type theory**.

    - **Type theories** are discontinuous (either/or), while **trait theories** are continuous (continuum).
    - Eysenck concurs with Cattell that psychology's goal is to **predict behavior**.
    - Eysenck suggests **not more than three supertraits (types)** are needed to account for most human behavior, contrasting with Cattell's 16+ traits.
    - Eysenck places **far more importance on genetic factors** than Cattell, but acknowledges environmental influence.
- **Hierarchical Taxonomy**
    - Eysenck's PEN model proposes a **hierarchical classification of personality** with four levels:
        - **Specific Responses:** Bottom level; individual behaviors (e.g., talking with a friend on a single occasion). Changeable across time/situation.
        - **Habitual Responses:** Second level; recurring behaviors (e.g., talking with friends on multiple occasions).
        - **Traits:** Third level; intercorrelated sets of habits (e.g., sociability).
        - **Supertrait/Type (Dimensions):** Top level; intercorrelated sets of traits (e.g., Extraversion). Stable.
    - **Reliability of measurement is increased** as superfactors are comprised of many items.
    - Eysenck uses "type" to refer to **dimensions normally distributed along a continuum**, similar to traits, not implying discontinuity.
- **Three Dimensions of Personality (PEN Model)**
    - Eysenck advocates for three major dimensions or superfactors:
        - **Extraversion-Introversion (E):**
            - **High Extraversion:** Sociable, popular, optimistic, rather unreliable.
            - **Low Extraversion (Introversion):** Quiet, introspective, reserved, reliable.
            - Traits like activity, liveliness, assertiveness correlate with sociability, defining extraversion.
        - **Emotional Stability versus Instability (Neuroticism) (N):**
            - **High Neuroticism:** Anxious, worried, moody, unstable.
            - **Low Neuroticism (Stability):** Calm, even-tempered, carefree, emotionally stable.
        - **Psychoticism versus Impulse Control (P):**
            - **High Psychoticism:** Troublesome, uncooperative, hostile, socially withdrawn. Often egocentric, impulsive, insensitive to others, opposed to social customs.
            - **Low Psychoticism (Superego Strength):** Altruistic, socialized, empathic, conventional.
            - Eysenck suggested psychoticism is a **genetic predisposition** toward psychosis or psychopathy, more common in men.

    - These three superfactors are **orthogonal** (do not correlate with each other).
    - Individuals can show **degrees of these superfactors** on a continuum (e.g., high extraversion, moderate neuroticism, low psychoticism).
- **Causal Aspects / Neurophysiological Basis of Traits and Types**

    - PEN model seeks **psychophysiological, hormonal, and biological mechanisms** for personality dimensions.
    - **Extraversion and Cortical Arousal:**
        - Related to **levels of cortical arousal** via the **ascending reticular activating system (ARAS)**.
        - **Introverts are chronically more cortically aroused** than extraverts; highly sensitive to stimulation, avoid overwhelming situations.
        - **Extraverts are under aroused** and insensitive to stimulation; constantly seek excitement.
        - Measured by skin conductance, brain waves, sweating.
        - Based on Yerkes-Dodson law: intermediate arousal is optimal for performance.
        - *Lemon Drop Test:* Introverts secrete almost twice as much saliva as extraverts when lemon juice is placed on tongue, due to ARAS differences.
    - **Neuroticism and Visceral Brain Activation:**
        - Reflects degree to which **autonomic nervous system reacts to stimuli**. Linked to the **limbic system (visceral brain)**, which influences motivation and emotional behavior.
        - **Neurotic individuals have greater activation levels and lower thresholds** within the visceral brain; easily upset by minor stresses.
        - Emotionally stable people are calmer due to lesser activation levels and higher thresholds.
        - Measured by heart rate, blood pressure, skin conductance, sweating, breathing rate, muscular tension.
    - **Psychoticism and Gonadal Hormones:**
        - Biological explanation involves **gonadal hormones (e.g., testosterone) and enzymes (e.g., monoamine oxidase - MAO)**.
        - Low platelet MAO found in psychotic patients and relatives, suggesting vulnerability marker.
    - **Psychopathology:** Psychological disorders arise from **genetic predispositions interacting with environment**.
        - High introversion + neuroticism = prone to anxiety disorders (phobias, obsessions, compulsions).
        - High extraversion + neuroticism = risk for psychopathic (antisocial) disorders.
- **Measurement of Personality**

    - Eysenck used **self-reports, observer ratings, biographical information, physique/physiology assessments, and objective physiological tests**.
    - **Eysenck Personality Questionnaire (EPQ):** Self-report questionnaire to assess the three supertrait dimensions. Includes a **lie scale** to detect faking. Junior EPQ for children 7-15.
- **Differences between Introverts and Extraverts (as measured by EPQ)**
    - Excitement enhances extravert performance but interferes with introverts.
    - Introverts prefer theoretical/scientific vocations (e.g., engineering, chemistry), extraverts prefer people-oriented jobs (e.g., sales, social work).
    - Introverts report more masturbation, extraverts engage in sexual intercourse earlier, more often, with more partners.
    - Introverts attain higher college grades.
    - Students withdrawing from college for psychiatric reasons tend to be introverts; for academic reasons, extraverts.
    - Introverts show higher arousal mornings, extraverts evenings.
    - Introverts work better in the morning, extraverts in the afternoon.

Unit 4: The Big Five Factors: The Basic Dimensions of Personality

- **Introduction and Definition**
    - Research indicates there may be **only five key or central dimensions of personality**, identified through factor analysis.
    - The Big Five are an empirically derived **descriptive model or taxonomy** of personality traits, not a specific theory.
    - They integrate diverse personality descriptions into a common framework.
    - Derived from people's descriptions of themselves and others in **natural language** (lexical hypothesis).
- **Discovery of the Big Five**
    - Allport and Odbert's classifications provided initial structure. Cattell (1943) reduced 4500 trait items to 35 variables, identifying 12 personality factors for his 16 PF.
    - **Fiske (1949)** simplified Cattell's 22 variables, finding clusters they called the **Big Five**.
    - Replicated by Norman (1967), Smith (1967), Goldberg (1981), and McCrae & Costa (1987).
    - Initially labeled as: **Extraversion or Surgency, Agreeableness, Conscientiousness, Emotional Stability versus Neuroticism, and Culture**. These summarize large numbers of specific personality characteristics.
- **The Big Five Theory - Key Terms**

    - **The Big Five:** A **taxonomy of personality traits**; a coordinate system mapping trait correlations in descriptions/ratings. An **empirically based phenomenon**, not a theory.
    - **Five-Factor Model (FFM):** Often used interchangeably with "Big Five," but originally associated with **questionnaire studies**. Descriptive framework.
    - **Five-Factor Theory (FFT):** McCrae and Costa's specific theory; views Big Five dimensions as **causal personality dispositions** with a **substantial genetic base** from biological structures/processes. Traits are basic tendencies, while attitudes, roles, goals are characteristic adaptations (interaction of tendencies and environment). FFT posits learning/experience play little part in influencing Big Five.
- **The Five Factors (OCEAN)**
    - **Openness to Experience (also Intellect/Imagination):** Broad range of interests, imaginative, insightful, artistic, creative, intellectual, scholarly.
    - **Conscientiousness:** High levels of thoughtfulness, good impulse control, goal-directed behaviors, organized, thorough, planful, dependable, hard-working, responsible, systematic, mindful of details.
    - **Extraversion (also Surgency):** Talkative, energetic, assertive, excitable, sociable, high emotional expressiveness, active, gregarious.
    - **Agreeableness:** Sympathetic, kind, affectionate, trust, altruism, modesty, prosocial behaviors, amiable, helpful, trusting.
    - **Neuroticism (reversed: Emotional Stability):** Emotional instability, anxiety, moodiness, irritability, sadness, tense, afraid, nervous, temperamental.
    - These are **broad dimensions**, not discrete types; people vary continuously.
- **Theoretical Perspectives on the Big Five**
    - **Interpersonal Theory:** Big Five describe enduring patterns of recurrent interpersonal situations. Interprets dimensions in terms of interpersonal implications.
    - **Socioanalytic Theory (Hogan, 1996):** Traits are socially constructed to serve interpersonal functions; trait terms are about reputation, leading to self-deceptive bias in self-reports.
    - **Evolutionary Theory (Buss & Shackelford, 1997):** Humans evolved "difference detecting mechanisms" for survival/reproduction; Big Five represent salient individual differences for survival needs.
    - **McCrae and Costa's Five-Factor Theory (FFT):** Big Five are causal personality dispositions with a substantial genetic base; basic tendencies (traits) are stable, while characteristic adaptations (attitudes, roles) change.
    - **Social Investment Theory (Brent Roberts):** Interactionist approach where environmental influences (social roles) combine with biological influences in shaping traits.
- **Advantages of the Big Five Structure**

    - Provides a common, understandable framework and **integrative descriptive model** for personality.
    - Captures commonalities among existing personality description systems.
    - Some dimensions (Extraversion, Neuroticism) are explained physiologically.
    - Useful model for organizing **reality-based person perception**.
    - Measures predict educational/occupational attainment, marital success, health habits, longevity.
- **Important Characteristics of the Five Factors**

    - **Dimensions, not types:** Continuous variation.
    - **Stable** over a 45-year period from young adulthood.
    - **Heritable** (genetic), at least in part.
    - Probably had **adaptive value** in prehistoric environments.
    - Considered **universal**, found in diverse languages (German, Chinese).
    - Knowing one's placement is useful for **insight and therapy**.
- **Measurement of the Big Five**

    - **Big Five Inventory (BFI):** Brief (44 items), self-report, short phrases, accessible vocabulary. Free for noncommercial research.
    - **International Personality Item Pool (IPIP):** Public domain scales analogous to commercial NEO PI-R.
    - **Big Five Aspect Scales (BFAS):** 100-item measure scoring Big Five factors and two "aspects" of each. Public domain.
    - **Saucier's mini-markers:** 40 single adjectives with excellent reliability/validity. Public domain.
    - **NEO PI-R:** 240-item commercial inventory (Costa & McCrae) measuring Big Five and six "facets" (subordinate dimensions) of each. NEO-FFI is a 60-item truncated version.
    - **Ten Item Personality Inventory (TIPI):** Super-short measure.
    - **Personality traits** are a narrower concept than the everyday usage of the term; other units like motivations, emotions, attitudes, etc., are conceptually distinct. A Big Five profile is only a partial description of personality.
    - **Shortcoming:** Several important personality traits (e.g., impulsive, sensation-seeking) lie beyond the Big Five and are poorly captured by natural language terms.

Block 4: Assessment of Personality

Unit 1: Introduction to Assessment and Testing

- **Introduction to Personality Assessment**

    1. **Personologists** study individual differences:

        - **Ways people differ** (using concepts like trait, type, motive, value, temperament).
        - **Ways of measuring individual differences** (assessment).
    2. Formal assessment provides **meaningful and exact information** about individual differences, enabling clear communication.
- **History of Personality Assessment**

    1. **Ancient Times:**
        - **1000 B.C.:** Written tests in China for civil service.
        - **1850 (USA):** Civil service examinations began.
        - **Greek Physicians (Hippocrates, Galen, 190 AD):** Theorized four body fluids (**humors**) and corresponding **temperaments** (sanguine, phlegmatic, choleric, melancholic). Believed balance of humors resulted in a healthy body.
        - **Avicenna (Muslim physician):** Introduced humors to Arab world, analyzed other illness reasons.
    2. **Foundations of Psychological Testing:**
        - **Wilhelm Wundt (1879 AD):** Founded first psychology lab, distinguished human body from personality, theorized **four temperaments as four dimensions of human personality**.
        - **James Cattell (1890):** Developed mental tests for college students (strength, pain resistance, reaction time).
        - **Binet and Simon (1905):** Developed the **Binet-Simon scale of mental development** for classifying mentally retarded children in France.
        - **Terman (1916):** Introduced **Intelligent Quotient (IQ)** with the Stanford-Binet Test.
        - **Between 1920-1940:** Factor analysis used to devise projective and personality tests.
    3. **Contributors to Personality Assessment Methods (20th Century):**
        - **Eduard Spranger (1905):** German philosopher, theorized four attitudes towards ethical values: artistic, religious, theoretic, economic.
        - **Hugo Munsterberg:** Devised the first personality test for employers to aid hiring decisions based on desired employee qualities.
        - **Ernest Kretchmer (1920):** German philosopher, presented theory of four character styles (hypomanic, depressive, hyperesthetic, anesthetic).
        - **Erich Fromm:** German philosopher, identified four human orientations: exploitative, hoarding, receptive, marketing.
        - **Carl Jung (1922):** Swiss psychologist, theorized people prefer identifiable behaviors and can be divided into personality types based on preferences.
        - **Myers Briggs and Katherine Briggs (1958):** Applied Jung's theory to develop **Myers-Briggs Type Indicator (MBTI)**, based on four questions:
            - Preferred energy source (Internal/External: Extroversion/Introversion)

        - Preferred perception source (Senses/Intuition: Sensing/Intuition)
        - Preferred decision-making (Logics/Feelings: Thinking/Feeling)
        - Preferred lifestyle (Ordered/Adaptable: Judgment/Perception)
    - **David Kiersy:** Associated four temperaments (Guardian, Rational, Idealist, Artisan) with Myers-Briggs cognitive functions, developed "Temperament Sorter".
        - *Example:* A "Guardian" values responsibility, security, service, system.
4. **Assessment Centers:**
    - **German Government (1920s):** Established programs for selecting officer candidates, inventing the modern assessment center (intensive evaluation with interviews, job simulations).
    - **British Government (WWII):** Modeled War Office Selection Boards (WOSB) on German method, found assessment centers superior for identifying combat leaders.
    - **U.S. Office of Strategic Services (OSS) (1942):** Used German assessment center model to screen applicants.
        - **Key features of OSS approach:** Selected based on competence, consistently evaluated validity, Eysenck (1953) showed paper-and-pencil tests comparable to longer assessment centers.
5. **Recent Developments:** The **"Five Factor Model"** (Big Five) emerged, showing order beneath diverse personality tests and predicting occupational performance.

- **Important Steps in Personality Assessment**

1. **Stipulate the agenda:** Focus on forecasting individual differences in a person's potential for getting along and getting ahead.
2. **Decide which aspect to measure:**
    - To assess "inside identity" (person/culture fit), use **value measures**.
    - To assess "outside reputation" (occupational performance), use **observer ratings** (e.g., 360-degree feedback).

- **Personality Assessment and Related Fields (Older/Non-Scientific)**

1. **Astrology:** Predicts personality and future based on planetary positions at birth.
2. **Biorhythms (Wilhelm Fleiss, George Thommen):** Day-to-day effectiveness governed by fixed physical, emotional, mental cycles from birth.
3. **Palmistry:** Interprets individual character from irregularities and folds of the hand.
4. **Humoural Theory (Ancient, Middle Ages):** Proposed four ingredients (blood, phlegm, yellow bile, black bile) whose proportions determined complexion (personality), physical/mental qualities, and dispositions.
5. **Somatotype Theory (Sheldon):** Divides people into three major body types, each with a specific innate personality.
    - **Ectomorph:** Thin and fragile; quiet, fragile, restrained, non-assertive, sensitive.

        - **Mesomorph:** Powerful and muscular; active, assertive, vigorous, combative.
        - **Endomorph:** Round, soft, and fat; relaxed, sociable, tolerant, comfort-loving, peaceful.
        - Personality determined by relative proportions of body types, as individuals are combinations.
- **Influence of Psychological Assessment**

    1. Roots in individual differences study, spurred by **Darwin's work on evolution**.
    2. **Sir Francis Galton:** Pioneer in studying inheritance of differences, direct behavior samples.
    3. **James McKeen Cattell (US):** Influenced by Galton, studied psychophysics, perception, reaction time, leading to intelligence tests.
    4. **Binet:** Investigations into mental functioning (including personality), used tasks like telling stories about pictures and identifying inkblots, paving the way for projective tests.
    5. **Karl Pearson and Charles Spearman:** Developed statistical procedures crucial for later assessment work.
- **Meaning and Purpose of Personality Assessment**

    1. **Meaning:** Personality refers to the **total functions of an individual interacting with the environment**. Assessment describes a person in terms of **measurable factors like traits**, which are inferred from consistent behavior.
    2. **Purpose (Nunnally, 1979):** Study four broad types of traits:
        - **Social Traits:** Determine how persons interact with others (e.g., friendliness, honesty, dominance, shyness). Includes temperament and character.
        - **Motives:** Non-biological drives (e.g., need to earn money/prestige, academic achievement, affiliation, aggression); constitute **personality dynamics**.
        - **Personal Conceptions:** People's attitudes toward self/others, values, interests.
        - **Adjustment:** Establishment of satisfactory relationships; process of finding suitable behavior modes to environment. Includes freedom from emotional worries, instability.
    3. These four types of traits are **correlated** and influence each other (e.g., dominance influences motives, personal conceptions, adjustment).
- **Testing and Measurement Concepts (Criteria for Scientific Acceptability)**

    1. **Standardisation: Uniform procedures** in administration and scoring of an assessment tool. Includes instructions on conditions, sample groups, scoring, and interpretation.

2. **Norms (Test Norms):** Information comparing a **raw score** to a representative group, indicating its rank (low, high, average). Usually converted to **percentile scores**.
3. **Reliability: Consistency or stability** of an assessment technique. Repeated administrations should yield reasonably same results.
    - **Test-retest reliability:** Consistency of scores over time (correlation of first and second administration). Coefficients usually above +.70.
    - **Split-half (Internal) reliability:** Consistency of scores across items within a test (correlating odd-numbered vs. even-numbered items).
    - **Parallel forms reliability:** Correlation of two versions of the same test (similar items) administered to the same group.
    - **Inter-scorer reliability:** Agreement between two or more judges in scoring the same test, crucial for subjective interpretations (e.g., projective data). Increased by explicit scoring rules.
4. **Validity:** Whether a test **measures what it intends to measure or predicts what it's supposed to predict**.
    - **Content Validity:** Items must be **representative of the entire domain or dimension** it measures. Determined by expert agreement.
        - *Example:* Shyness test should reflect personal, social, cognitive aspects of shyness.
    - **Criterion-Related Validity:** Extent to which a test **accurately forecasts some agreed-upon criterion**. Determined by correlating test scores with independently measured criterion.
        - **Predictive Validity:** Capacity to predict future criterion behavior (e.g., intelligence test predicting school performance).
        - **Concurrent Validity:** Extent to which a test correlates significantly with another currently derived test or existing criterion measure (e.g., paranoid test correlating with clinical diagnosis without criterion contamination).
    - **Construct Validity:** How well a test measures a **hypothetical construct** (abstract invention). Laborious process of gathering evidence from correlations with related measures.
        - **Convergent Validity:** Correlates test scores of the construct with scores from **another test purportedly measuring the same construct**.
        - **Divergent (Discriminant) Validity:** Shows the assessment tool **does not correlate with measures of qualities it was not intended to measure**.

Unit 2: Approaches to Personality Assessment (Self-Report, Problems of Response in Projective and Behavioural Assessment)

- **Self-Report Personality Tests (Inventories)**

    - **Definition:** Self-rating questionnaires where individuals describe their own feelings, environment, and reactions.
    - **Classification based on purpose/content:**
        - Measure specific traits (e.g., self-confidence, dominance, extraversion).
        - Evaluate adjustment to different environments (e.g., school, home, health).
        - Evaluate pathological traits (e.g., MMPI for many, 16 PF for some).
        - Screen individuals into groups (e.g., Cornell Index for psychosomatic difficulties).
        - Measure attitudes, interests, values (e.g., Bogardus Social Distance, Strong Vocational Interest Blank, Allport-Vernon Study of Values).
    - **Principle:** Behavior is manifestation of trait; presence/absence of trait found by assessing behavior.
    - **General Features:** Paper-and-pencil tests, ask questions with limited prescribed choices (e.g., Yes/No, True/False). **Objectivity achieved by restricting response freedom** and **standardized scoring procedures**.
    - **Single-Trait Tests:** Measure specific aspects of personality; scores reflect stable individual differences.
        - *Examples:* Locus of Control Scale (Rotter), Sensation Seeking Scale (Zuckerman), Self Monitoring Scale (Snyder).
    - **Multidimensional Tests:** Measure several personality dimensions simultaneously; provide comprehensive overview.
        - *Examples:* **Sixteen Personality Factor Questionnaire (16-PF)** (Cattell), **Neuroticism/Extraversion/Openness Personality Inventory (NEO-PI)** (Costa & McCrae), **Myers-Briggs Type Indicator (MBTI)** (Jung-based), **Minnesota Multiphasic Personality Inventory (MMPI)**.
- **Strengths of Self-Report Tests**
    - Provide **thorough, precise, and systematic information**.
    - **Objectivity of scoring minimizes personal or theoretical bias**.
    - **Easily administered** by those with little formal training.
    - Generally have **greater reliability**.
    - Multidimensional inventories allow for **measurement of several traits at once**.
- **Weaknesses and Faking in Personality Inventories**
    - **Deliberate Deception (Faking):** Occurs when person believes there's gain from fraudulent responding.
        - **"Faking good":** Presenting oneself favorably (e.g., job applicant).
        - **"Faking bad":** Presenting oneself as psychologically disturbed (e.g., criminal competency assessment).
    - **Social Desirability Bias:** Tendency to respond in ways that "look good," often unconsciously.

    - **Response Set (e.g., Acquiescence):** Tendency to respond in a particular way regardless of item content (e.g., always agree/disagree or true/false). This distorts scores.
- **Measures to Overcome Weaknesses (Avoid Faking)**
    - **Safeguards/Validity Scales:** Built into tests (e.g., MMPI) to detect lying, defensiveness, evasiveness.
    - **Filler Items:** Make test purpose less obvious.
    - **Careful Evaluation of Social Desirability of Items:** Before inclusion in test.
    - **Phrasing Items:** To balance "true" or "yes" bias in acquiescence response set (e.g., half items positive, half negative).
    - **Establishment of Rapport:** Warm, cooperative relationship with testees reduces discomfort and encourages truthfulness.
    - **Forced-Choice Technique:** Subject chooses between equally desirable/undesirable terms/phrases, outwitting faking.
    - **Concealing Main Purpose of Test:** Stating a plausible but false purpose or inserting false information (e.g., fictitious book titles).
    - **Use of Verification and Correction Keys:** Indicate if subject is projecting a true picture of self (e.g., MMPI's four validity scores checking carelessness, evasiveness, misunderstanding).
    - **Important decisions should not be based on self-report data alone**.
- **Some Important Personality Inventories (Detailed)**
    - **Woodworth Personal Data Sheet (1918):** First personality questionnaire, 116 questions on neurotic tendencies to screen WWI soldiers.
    - **The Sixteen Personality Factor Questionnaire (16 PF) (Cattell):** 187 items, measures **16 source traits** (trait dimensions/continuums). Used for counseling, employment decisions.
        - *Example:* Reserved/Outgoing dimension with many degrees.
    - **Neuroticism/Extraversion/Openness Personality Inventory (NEO-PI) (Costa & McCrae):** Based on the **Five-Factor Model**.
    - **Myers Briggs Type Indicator (MBTI) (Myers-Briggs, based on Jung):** Looks at four dimensions:
        - **Sensing/Intuition (S/I):** Rely on physical senses/facts (S) vs. patterns/hunches/possibilities (I).
        - **Thinking/Feeling (T/F):** Use logic/analysis (T) vs. personal values/emotional reactions (F).
        - **Introversion/Extraversion (I/E):** Classic Jungian dimension.
        - **Perceiving/Judging (P/J):** Adaptable/spontaneous/put off decisions (P) vs. action-oriented/decisive/get task done (J).
        - Combines into 16 personality types (e.g., INTJ, ISTP). Used for career guidance.

- **Minnesota Multiphasic Personality Inventory (MMPI) / MMPI-2 (Hathaway & McKinley, 1943):** Most common personality inventory, specifically tests **abnormal behavior patterns**.
    - **MMPI-2 (1989):** Updated, restandardized version with 567 True/False/Cannot Say items. Modified sexist/outmoded wording, eliminated objectionable items, national norms.
    - Has **10 clinical scales** (e.g., hysteria, paranoia, depression, schizophrenia) and **8 validity scales**.
    - **Validity scales** detect if respondents are lying, defensive, evasive (e.g., lie scale for social desirability/untruthfulness, repeated items to check consistency).
    - **Interpretation Approaches:**
        - **Clinical:** Expert inspects scale scores, notes profile features, adds personal experience.
        - **Actuarial:** Compares profile to previous profiles, uses statistical base rates/norms for diagnosis/therapy.
    - Used in clinical settings, job recruitment, family dynamics, substance abuse, suicide, rehabilitation. Translated into 125 languages.

- **Projective Techniques**

    - **Purpose:** Primarily to assist clinical psychologists in diagnosing emotional disturbance and **uncovering unconscious conflicts, fears, and concerns** (based on Freud's theory).
    - **Definition (Frank, 1939):** Present people with **ambiguous stimuli** for which there is no obvious culturally defined response; people "project" feelings, needs, attitudes onto material.
    - Responses reveal "pent up impulses," "ego defenses," etc..
    - **Common Features:**
        - Use **ambiguous or unstructured test stimuli** (e.g., inkblots, vague pictures).
        - Test taker not told purpose or how responses are scored/interpreted.
        - Instructions emphasize **no correct/incorrect answers**; free response.
        - Scoring/interpretation relies heavily on **subjective clinical judgments**.
    - **Classification (Lindzay, 1959):**
        - **Association Technique:** Respond with associations evoked by stimuli.
            - *Examples:* **Rorschach Test** (inkblots), Holtzman Inkblot Test, Word Association Test. Reaction time and responses analyzed.
        - **Construction Technique:** Construct a story from stimulus materials (pictures).
            - *Examples:* **Thematic Apperception Test (TAT)**, Children's Apperception Test (CAT), Rosenzweig Picture Frustration Test. Themes and response mode considered.
        - **Completion Technique:** Complete incomplete sentences.

        - *Examples:* Sack's Sentence Completion Test, Madeline Thomas Completion Stories test. Lack uniform analysis.
    - **Expressive Technique:** Express personality through manipulative tasks (play, drawing, role-playing, painting). Focus on **process/way of handling materials**.
    - **Choice Technique (Ordering Technique):** Choose most relevant picture from sets, or rank pictures based on preferences. Less "projective".
        - *Example:* Szondi test (ranking pictures on like-dislike).
- **Strengths and Weaknesses of Projective Techniques**
    - **Strengths:**
        - Stimuli are ambiguous, so person **doesn't know how information is gathered**, reducing intentional deception.
        - Indirect method **circumvents conscious defenses**, sensitive to hidden aspects of personality.
        - Capable of revealing personality in **greater depth and detail** than self-inventories.
    - **Weaknesses:**
        - Generally **not well standardized** (administration, scoring, interpretation).
        - Scoring relies on examiner's skill/intuition, leading to **low reliability** (especially inter-scorer reliability). Extensive training in specific scoring systems can improve reliability.
        - Interpretation of scores is often subjective.
        - **Little convincing evidence for validity**.
        - Psychologists are advised **not to base diagnosis solely on projective tests**; should be combined with interviews, case histories, self-reports.
        - **Time-consuming** to administer and score.
- **Behavioural Assessments**
    - Behaviorists assume personality is **habitually learned responses to stimuli**; prefer to watch behavior unfold in real world.
    - **Observation Techniques:**
        - **Direct Observation:** Psychologist observes client in **ordinary, everyday behavior**, preferably in natural settings (home, school, workplace).
            - *Example:* Observing tantrums to link to fine motor difficulties.
        - **Naturalistic Observation:** Observing and recording behavior as it naturally occurs, but systematically. Rich source of information about what people do in natural environments.
            - *Examples:* Children's play patterns, antisocial adolescent behavior, eating habits, leadership styles.
            - **Limitations:** Observers at mercy of unpredictable events, observer bias/expectations, questionable generalization/reliability/validity from few people/situations, observer interference.

- **Situational Tests:** Compromise between standardized tests and observation.
  - Measure traits based on observations/ratings of what person thinks/does in a **simulated real-life situation**. Subject usually unaware of being studied.
  - Suited for leadership, dominance, responsibility, extraversion-introversion.
  - **Behavioral Tests:** Situational tests using directly observable units of behavior for character traits (e.g., honesty, self-control, cooperation).
    - *Example:* **Character Educational Inquiry (CEI) tests** (Hartshorne, May & Shuttleworth, 1930) for honesty in school children, using "duplicating technique" to detect cheating.
  - **Advantages:** Findings can be easily generalized to natural life situations.
  - **Limitations:** Extremely **time-consuming, costly, laborious**; demand trained observers. Subjectivity and bias may operate. Focus on isolated behavior bits. "What to observe" is a problem. Observer visibility can alter group behavior.
- **Other Behavioral Measures:**
  - **Rating Scale:** Numerical rating assigned by assessor or client for specific behaviors.
  - **Frequency Counts:** Literally counts frequency of certain behaviors within specified time.
- **Weaknesses in Behavioral Assessment Tests:**
  - **Observer effect:** Person's behavior affected by being watched.
  - **Observer bias:** Can be controlled by multiple observers.
  - No control over external environment.
  - Specific behavior may not occur during observation time.
  - Difficult to draw conclusions based on behavioral methods alone; need standardized tests.

Unit 3: Behavioural Assessment

- **Definition of Behavioural Assessment**
  - Assessing and measuring constituents of behavior to determine **why it occurs and what causes it**. Includes overt behaviors, feelings, cognitions, and their controlling variables (internal/external).
  - Focuses on **what a person does** rather than what they have or are.
  - Exploratory activity to find procedures to understand individuals.
  - Goal: **Identify appropriate intervention strategies** to remediate specified behavior problems.
  - Main goal has been **behavioral change**.
- **Theoretical Model/Common Characteristics and Assumptions**
  - Underpinned by **interaction between previous learning and external/organismic environments**.
  - Setting where behavior occurs is primary; biological makeup helps adapt.

    - Assessment evaluates the **person, the setting, and their interaction**.
    - **Common Characteristics**:
        - Focus on **behavior** (overt and covert in specific situations).
        - Belief in **quantification** (for reliable comparisons and objectivity).
        - Use **trained, impartial observers**.
        - Use **empirically validated measures**.
        - Recognize and **minimize errors** using statistical methods.
        - Believe behavior occurs due to **environmental stimuli** (focus on public events, direct observation).
        - Depend on **multiple sources of information** (interviews, checklists, rating scales, self-reports, observations).
        - High emphasis on **intervention** (tailoring assessment to person/situation for change).
        - Use **continuous assessment** (baseline, intervention, follow-up).
        - Emphasize **empirically based decision making**.
        - Focus on **individual person** rather than group comparisons (idiographic).
        - High emphasis on **individual differences** (relative to situation/culture).
        - Look for causes to **solve problems**.
        - Focus on developing **adaptive, positive, desirable behavior**.
- **Advantages and Limitations of Behavioural Assessment**
    - **Advantages:**
        - Provides **objective data** for instructional content and intervention strategies.
        - Leads directly to **formulation of intervention strategies**.
        - Can be undertaken in **natural or simulated settings**.
        - Tailored to **unique characteristics** of individual.
        - Effective for **evaluating treatment outcomes**.
        - Variety of techniques allows **multifaceted assessment**.
        - Most techniques can be implemented by anyone with sufficient training.
    - **Limitations:**
        - Much methodology is **not standardized**.
        - Differing levels of behavior specification may result in **inconsistent data**.
        - Narrow definitions of behavior may result in **less consistency** in observation.
        - Requires **trained psychologists/behaviorists**; defective assessment if untrained.
- **Functional Behavioural Assessment (FBA)**
    - Looks beyond behavior as "bad" to determine its **function for the individual**.
    - First step to stopping behavior: understanding *why* it occurs.
    - Process involves **documenting behavior in different situations**, interviewing family/workplace members.
    - Provides information necessary for **effective remedial strategies**.

- **Reliability and Validity Issues in Behavioural Assessment**
    - **Reliability:** Agreement between observers (inter-rater reliability) or a single observer over time (intra-rater reliability).
    - **Validity:** Data from one measure predictive of behavior from other measures/settings (convergent validity).
    - **Treatment validity:** Extent to which multifaceted assessment leads to beneficial treatment outcomes.
- **Uses of Behavioural Assessment**
    - **Screening, problem identification and analysis, selection of intervention program**.
    - **Continuous assessment:** Continues after intervention to evaluate effectiveness (e.g., if treatment was administered as planned, if changes monitored, if changes due to treatment, cost-effectiveness, need for modification/maintenance).
- **Types of Behavioural Assessment**
    - **Direct assessment:** Recording behavior as it occurs in the situation.
    - **Analogue assessment:** Measuring behavior under simulated conditions (e.g., role play).
    - **Indirect assessment:** Behavior inferred through retrospective analysis.
    - **Idiographic assessment:** Describes individual behavioral characteristics; disorder-focused (e.g., ADHD child).
    - **Contextual assessment:** Not explicitly defined in this list but implied by "triple response mode" and "multi-causality".
    - **Triple Response Mode:** Behavioral problems defined through **motor, cognitive, physiological modes**.
        - *Example:* Depression defined by cognitive (loneliness), physiological (sleep), motor (low social behavior).
    - **Multicausality:** Problems explained by several conditions (e.g., reinforcement deficit, motivational dysfunction, biological conditions, and their interaction).
    - **Multimethodism:** Use of various assessment methods beyond just observing overt behavior.
    - **Experimental Method:** Constant feature due to need for treatment and evaluation of change.
- **Process of Behavioural Change: Assessment, Treatment, and Evaluation**
    - First, **assess why behavior occurs**; then formulate **treatment intervention**, and **evaluate** if desired change occurred.
- **Case Study Method**
    - **Definition: Detailed study of a single individual's behavior over an extended period**. Used in clinical/medical settings for diagnosis and treatment of psychological problems.

- Clinician seeks understanding of life experiences/behavior patterns through recollections, interviews with others, documents, psychological tests. Searches for past/present clues for difficulties.
- Important in development of personality theories (e.g., Freud's psychodynamic theory based on intensive single cases; Carl Rogers relied on client case studies).
- **Purpose:** Understand important aspects of a unit's life cycle; longitudinal approach. Focus on **typicalness rather than uniqueness**. Can suggest deep insights and offer hypotheses for rigorous experimental procedures.
- *Example:* Harvard "personologists" (Murray et al., 1938) studied college males in-depth, using questionnaires, projective tests, biographical data, experiments, stress interviews, group settings; produced rich narrative accounts.
- **Types:**
  - **Individual Case Study:** Social unit is one individual; emphasizes in-depth analysis; useful for hypothesis development, not broad generalizations.
  - **Community Case Study:** Social unit is a family or social group; thorough observation and analysis of group living in a geographical territory (e.g., location, economy, social structure).
  - **Deviant Case Analysis:** Researcher starts with difference between people/groups and deduces conditions that produced the difference.
  - **Isolated Clinical Case Analysis:** Analytical problem popular in psychoanalysis; Freud's study of Little Hans is an example.
- **Strengths:**
  - Provides **complexities and idiosyncrasies** of personality not possible otherwise.
  - Most appropriate for studying **processes in one/few persons** and coping with life experiences.
  - Only way to study **rare instances** of a phenomenon.
  - Rich source of information, can offer **intriguing hypotheses**.
- **Weaknesses:**
  - Cannot be totally certain about **cause-and-effect relationships** (cannot control factors).
  - **Limited generalizability** (examines only one person).
  - Data may be **retrospective or second-hand**, distorted by time.
  - Conclusions may reflect **personal biases of investigator**.

- **Interview Method**

  - **Meaning and Purpose:** Oldest and widely used method for collecting information. Face-to-face dialogue for specific goals (e.g., employment assessment, research, clinical diagnosis).
  - Used to measure specific personality aspects (e.g., Type A behavior pattern by asking "What do you do when you are stuck on the highway behind a slow driver?").

- **Types:**
  - **Structured Interview:** Questions carefully worded and presented in a **prescribed order**. Less threatening questions first to build trust. Preferred in research settings for **greater validity and reliability**.
    - *Example:* "How long have you been married?", "How many children do you have?".
  - **Unstructured Interview:** Allows person **considerable latitude in responding**. Interviewer can probe thoughts/feelings; more flexible. Preferred by clinical psychologists in therapeutic settings.
    - *Example:* "You feel that your spouse really lets you down," "That must have been a very stressful experience".
- **Strengths:**
  - Highly skilled interviewer can produce **valuable information** (communication, self-perception, anxiety, future plans, job satisfaction).
  - Well-planned interviews can be used in **hypothesis testing research**.
  - Rich source of personality data.
  - Indispensable assessment technique, especially with objective data.
- **Weaknesses:**
  - Data is **highly subjective** and may reflect **theoretical biases of interviewer**.
  - Interviewer's personality can influence truthfulness/disclosure.

- **Other Measures**
  - **Experience Sampling Method:** Researchers "beep" individuals at random/pre-established times to obtain **descriptions of behavior at those times**. Reveals stable patterns of individual behavior.
  - **Biological Measures:**
    - **Positron Emission Tomography (PET) scans:** See characteristic patterns of brain activity related to overt behavior.
    - **Hormone levels:** Investigate if aggressive persons have different sex hormone levels (e.g., Harris et al., 1996, suggests this may be the case for testosterone).

Unit 4: Other Measures of Personality

- **Self-Report Questionnaires and Inventories (Revisited and Expanded)**
  - Also known as **objective tests of personality**.
  - **Minnesota Multiphasic Personality Inventory (MMPI)**
    - Originally (1943) by Hathaway and McKinley to aid clinical diagnosis and evaluate psychotherapy effectiveness.
    - Used an **empirical strategy**: Administered hundreds of True/False items to groups with diagnosed psychological disorders.
    - Established **10 clinical scales** and **4 validity scales** (e.g., "lie scale" for socially desirable/untruthful responses).

        - **MMPI-2 (1989):** Updated, 567 items, modified for sexist/outmoded content, eliminated objectionable items, national norms.
        - **Interpretation: Clinical** (expert inspection, profile features, personal experience) vs. **Actuarial** (comparing to previous profiles, statistical base rates/norms).
        - Used in clinical settings, determining job compatibility, studies on family dynamics, eating disorders, substance abuse, suicide, rehabilitation readiness.
        - Main source of items for other tests (e.g., Taylor Manifest Anxiety Scale, Jackson Personality Inventory, California Psychological Inventory).
        - Translated into 125 foreign languages, showing popularity.
    - **Millon Clinical Multiaxial Inventory (MCMI) / MCMI-III (Millon, 1987, 1997):**
        - Objective measure, items correspond closely to **psychological disorder categories**. Especially useful for clinical psychologists in identifying problems for therapy.
        - **MCMI-III:** Adds **Grossman Facet Scales** for therapy guiding subscales, identifying salient clinical domains (interpersonal, cognitive) for "personalized therapy".
        - **Distinguishing Features:** Brevity, theoretical anchoring (Millon's theory), multiaxial format, tripartite construction/validation, use of base rate scores, interpretive depth.
        - **Administration:** Brief (20-30 mins), easy to read (8th grade level), self-administering.
        - **Scales:** 10 clinical personality pattern, 3 severe personality pathology, 6 clinical syndrome, 3 modifier indices, 1 validity index.
        - **Reliability:** Generally sound, Axis II scales highest stability. High point codes fairly stable. High internal consistencies (avg. .89 for clinical scales).
        - **Validity:** Extensive item overlap, also construct overlap (personality disorders not distinct).
        - **Norms:** Based on national sample of clinical subjects (DSM-III/III-R diagnoses).
        - Primarily used in **clinical settings** for mental health services.
    - **NEO-Personality Inventory (NEO-PI) / NEO PI-R (Costa & McCrae, 1989):**
        - Measures aspects of personality **not linked to psychological disorders**; focuses on the **"Big Five" dimensions**.
        - Highly regarded assessment, measures interpersonal, motivational, emotional, attitudinal, and personal style.
        - **Forms:** Form-S (self-reports), Form-R (observer reports).
        - Designed for general description of **normal personality** in clinical, counseling, educational situations.
        - **Five Domains/Factors and their Facet Scales**:
            - **Neuroticism:** Anxiety, Hostility, Depression, Self-Consciousness, Impulsiveness, Vulnerability.

            - **Extraversion:** Warmth, Gregariousness, Assertiveness, Activity, Excitement-Seeking, Positive Emotions.
            - **Openness to Experience:** Fantasy, Aesthetics, Feelings, Actions, Ideas, Values.
            - **Agreeableness:** Trust, Modesty, Compliance, Altruism, Straightforwardness, Tender-Mindedness.
            - **Conscientiousness:** Competence, Self-Discipline, Achievement-Striving, Dutifulness, Order, Deliberation.
        - **Reliability:** High internal consistency (.86-.95 for domain scales), stability coefficients from longitudinal studies (.51-.83).
        - **Validity:** Validated against other personality inventories and projective techniques.
        - **Uses:** Counseling, clinical settings, high school/college students, business/industrial settings, psychological research (e.g., sport psychology).
- **Ink Blot Tests**
    - Psychological tests where a subject's interpretation of **inkblots is analyzed**. Used to determine what a person perceives in **highly ambiguous shapes**.
    - **Rorschach Psychodiagnostic Test (Hermann Rorschach, 1921):**
        - Rorschach developed a system for psychological assessment based on varying* **Scoring Categories (Exner's Comprehensive System):**
            - **Location:** Where seen (whole blot, common/uncommon detail, white space).
            - **Determinant:** What aspect determined response (form, color, shading, movement, combinations).
            - **Content:** Anatomy, blood, clouds, fire, geography, nature, etc..
        - **Interpretation based on number of responses in categories and ratios:**
            - Good "whole" (W) responses = integrated thinking.
            - Color responses = emotionality, impulsivity.
            - Many detailed responses = compulsivity.
            - White-space responses = oppositional tendencies.
            - Movement responses = imagination.
            - Ratio of human movement to color responses (experience balance) = thought-minded vs. action-oriented.
            - Accuracy of responses (how well they fit blot) is important.
            - Delays = anxiety; few color/movement = depression; shading = self-control.
            - Original responses with poor form/confused thinking = psychotic process.
            - Total number of responses = rough index of mental ability.

        - Content interpretation is subjective (e.g., unreal characters = inability to identify with real people, masks = role playing, food = dependency, death = loneliness, eyes = sensitivity to criticism).
    - **Reliability and Validity:** After Rorschach's death, standardization attempts led to confusion until **Exner's Comprehensive System** (late 1950s). Critics argue interpretation is highly dependent on examiner's judgment, leading to **low reliability**.
- **Holtzman Inkblot Technique (HIT) (Holtzman, 1961):**
    - Projective personality assessment for ages five and above. Purpose: Assess personality structure, diagnose schizophrenia, depression, addiction, personality disorders.
    - Designed to **overcome Rorschach deficiencies**. *ile norms based on eight normal/pathological groups.
    - Procedures for construction/standardization more like personality inventories, hence **higher reliability than Rorschach**.

- **Apperception Test**

    - **Apperception:** Conscious perception with full awareness; process of understanding new qualities of an object by relating them to past experience. Leibniz introduced for mind's reflective thinking. Kant proposed empirical (ordinary consciousness) and transcendental (consciousness unifying experience) apperception.
    - In tests, involves **pictures or other materials** about which respondent tells a story.
    - Assume examinees project needs, desires, conflicts into stories and characters.
    - **Thematic Apperception Test (TAT) (Morgan & Murray, 1935):**
        - Based on **Murray's Need theory**.
        - Consists of **30 black-and-white picture cards** (plus 1 blank) depicting people in ambiguous situations, in overlapping sets for different demographics.
        - **Procedure:** Examinee tells a complete story for each of 10+ cards, including current events, thoughts/feelings of characters, preceding events, and outcome. (e.g., story about woman troubled by resentful memories of mother).
        - **Interpretation:** Skilled examiner obtains info on dominant needs, emotions, sentiments, conflicts. Subjective, impressionistic process focusing on **needs/personality of main character (hero/heroine)** (representing examinee) and **environmental forces (press)**. Frequency, intensity, duration of story also considered.
        - Certain responses indicative of mental disorders (e.g., bizarre themes for psychosis, hostility for paranoia, overcautiousness for OCD).
        - Scores from systematic procedures can be fairly reliable and interpreted with norms. Content influenced by environmental context; doesn't always differentiate normal/disordered.

        - Used with various ethnic and age groups; modifications for Blacks, children, older adults.
    - **Senior Apperception Technique (SAT):**
        - **16 stimulus pictures** for older adults, themes of loneliness, uselessness, illness, helplessness, lowered self-esteem, plus positive situations.
        - Responses reflect concerns over health, social relations, nursing homes.
        - Criticized for **inadequate norms and possible stereotyping of elderly**.
    - **Children's Apperception Test (CAT) (Bellak and Bellak, 1949):**
        - Projective personality test for children,.
        - Open-ended, encourages free expression of thoughts/feelings, revealing *how* individual thinks/feels.
        - Administered by trained professional (20-45 minutes).
